

Local villagers' perceptions of wolves in Jiuzhaigou County, western China

Yu Xu, Biao Yang, Liang Dou

While there have been increasing numbers of reports of human-wolf conflict in China during recent years, little is known about the nature of this conflict. In this study, we used questionnaires and semi-structured interviews to investigate local villagers' perceptions of wolves in Jiuzhaigou County, western China. We sampled nine villages with more frequent reports of wolf depredation to the local government, but included three villages near alpine pastures in which reports of depredation were less frequent. We sampled 100 residents, a subset of the local population who were more likely to have had experience with wolves. During the preceding three years, most families of the respondents grazed livestock on alpine pastures, and most of them reported that their livestock suffered from depredation by wolves. The mean value of the reported annual livestock loss rates was considerably higher in villages that reported depredation more frequently than in those with less frequent reports of depredation. Most respondents in the more frequently depredated villages perceived an increase in wolf populations, whereas many in the less frequently depredated villages perceived a decrease in wolf populations in their areas. People's attitudes towards wolves did not differ significantly between these two village categories. The majority of the respondents were negative in their attitude to wolves, despite a prevalent Tibetan culture that favors the protection of wildlife. People's negative attitude was directly related to the number of livestock owned by their family. Those with a larger number of livestock were more likely to have a negative attitude towards wolves. Factors such as village category, ethnicity, age and education level did not influence people's attitudes to wolves. We suggest that improved guarding of livestock and provision of monetary support on human resources and infrastructure may mitigate human-wolf conflicts in this region.

14 Introduction

15 Conflicts between wolves and humans are common worldwide, because of human fear of wolves and
 16 in particular, financial loss due specifically to injury to and loss of livestock that wolves cause (Mech
 17 & Boitani 2003; Treves & Karanth 2003; Bisi et al. 2007). As wolf populations expand or humans
 18 encroach on their habitats, economic losses to wolves increase and conflicts have become increasingly
 19 likely, presenting unique challenges for the conservation and management of wolves (Mech & Boitani
 20 2003; Naughton-Treves, Grossberg & Treves 2003; Bisi et al. 2007; Lescureux & Linnell 2013).

21 To conserve wolves, many researchers have conducted studies aimed at understanding the
 22 conflicts. Managers need to know the perceptions and attitude of local people to wolves and their
 23 conservation programs. In particular, by determining which people are more negative towards wolves,
 24 managers are potentially able to find solutions to improving people's tolerance towards wolves (Treves
 25 & Karanth 2003; Suryawanshi et al. 2013). It has been pointed out that people's attitude depends
 26 mainly on their residence, age, gender, education and income level, and former experience with wolves
 27 (for a review of 38 surveys see Williams, Ericsson & Heberlein 2002; Ericsson & Heberlein 2003;
 28 Naughton-Treves, Grossberg & Treves 2003; Røskoft et al. 2007; Skogen & Thrane 2007). Yet, it is
 29 hard to find a widely accepted management policy, because of regional variation and different factors
 30 affecting attitudes (Bjerke, Reitan & Kellert 1998; Bisi et al. 2007). Given this, one has to learn more
 31 about the characteristics of human-wolf conflicts and human attitudes towards wolves, especially for
 32 regions where conflicts have been reported frequently but available knowledge is very scarce.

33 China has a large wolf population which is mainly distributed in areas with relatively few
 34 anthropogenic changes, in the Qinghai–Tibet Plateau, the Mongolia Plateau and the Northeast Plain. In
 35 1998, the number of wolves in China was estimated as about 6,000 individuals (Wang 1998, Yang
 36 2008). In this year, wolves were listed as a vulnerable species in the China Red List (Wang 1998), and
 37 since then, all hunting has been banned for this legally protected animal. In 2003, China was estimated

to have a population of as many as 12,500 individuals (Mech & Boitani 2003). We are not aware of any more recent estimates, although the number is likely to have increased substantially in recent years. In recent years in China, there have been increasing reports of injury and loss wolves caused especially to livestock, resulting in increase in human-wolf conflicts (Yang 2008; Zhang et al. 2010; CNC 2012; Li et al. 2013; ScienceNet 2013). Yet, the published literature on this topic is scarce. There have not been any national policies relating to wolves other than some with indirect implications such as auctions of licenses for hunting wild animals (BBC News, 2006) and eco-compensation to mitigate human-wildlife conflicts (Xinhuanet 2014; Yunnan.cn 2014).

In this study, we examined local villagers' perceptions of wolves in Jiuzhaigou County, where wolf depredation on livestock has been reported increasingly and the local government is considering management plans for wolves. We aimed to determine wolf population trends, since there have been no data available on the wolf populations in this area. Furthermore, we aimed to determine the level of livestock depredation caused by wolves, and then how people's attitude toward wolves was related to socioeconomic variables, specifically religious belief (e.g., Liu et al. 2011) and livestock ownership (e.g., Tuğ 2005), which are poorly understood.

Methods

Ethics statement

The study conformed to the Declaration of Helsinki, and the Ethics Committee of Pingdingshan University approved the research protocol (Ref: 2012003). Verbal informed consent was obtained from all the subjects prior to participation.

Study area

We conducted the study in Jiuzhaigou County (N 32°53'–33°43', E 103°27'–104°26'; Fig. 1), Aba Tibetan and Qiang Autonomous Prefecture of northwestern Sichuan Province, western China. The

62 county lies at the northeastern edge of Qinghai–Tibet Plateau and is famous for its Jiuzhai Valley
 63 National Park and the traditional cultures of its inhabitants. The area is 5,290 km², with an elevation
 64 ranging from 1,000 m to 4,500 m. The climate is subtropical to temperate monsoon with a mean annual
 65 temperature of 12.7 °C. Total annual rainfall is 550 mm, with 80% of rainfall occurring between May
 66 and October. The county comprises 17 townships and 120 villages, inhabited by Tibetan, Qiang, Hui,
 67 Han and other ethnic groups. In 2011, the county’s population was 66,246, with a minority population
 68 (ethnic groups other than Han) of 25,090.

69 Jiuzhaigou County has 3,570 km² of forested lands (covering about 67% of the total area), and
 70 is the second largest forest area in Sichuan Province. It is rich in alpine grasslands, especially in the
 71 northern part, with an area of about 1,200 km² (Chen 2011). Livestock grazing occurs mainly in the
 72 northern region. Yaks are the most common livestock species grazed, but there are a few sheep and
 73 goats. Livestock are herded to alpine pastures except during extreme winter weather when they are
 74 herded in the cropland around the villages or are stall-fed inside the villages. Livestock of each village
 75 graze in exclusive pastures. Families take turns at herding the entire village’s stock. Commonly, a
 76 couple of people herd the livestock, with the use of one or two shepherd dogs occasionally. The
 77 livestock are usually left to range freely on the daytime. At night, the herders bring them back to
 78 protective corrals, which are poorly built with low walls and no roof.

79 Wolves are one of the most important animal species in the local ecosystems. Their large
 80 natural prey species are ungulate animals including *Elaphodus cephalophus*, *Capreolus capreolus*,
 81 *Capricornis sumatraensis*, *Naemorhedus goral*, and *Pseudois nayaur*; smaller prey include *Marmota*
 82 *himalayana*, *Lepus oiostolus*, and *Ochotona thibetana*, and some Galliformes such as *Tetraogallus*
 83 *tibetanus*, *Tetraophasis obscurus*, *Perdix hodgsoniae*, *Ithaginis cruentus*, *Pucrasia macrolopha*, and
 84 *Chrysolophus pictus*. However, prey abundance is low (SPAFS 2004; SCUSLS 2011). In the area,
 85 livestock depredation by wolves has been reported frequently in recent years, whereas there are few

86 reports on wolf attacks on humans. The local people reported that wolves usually traveled in groups,
87 and attacked livestock during both the day and night.

88 Fieldwork

89 We carried out the fieldwork in April and May 2012. Following advice from the local forestry bureau,
90 we conducted an interview survey in the northern region where many villages reported frequently
91 livestock depredation by wolves to the local government. We sampled nine villages with frequent
92 reports of depredation. For comparison, we also sampled three villages near alpine pastures in which
93 reports of depredation were less frequent (Fig. 1). The people we interviewed were those who were 16
94 years or older and who grazed their livestock, collected herbs or mushrooms, or carried out other
95 activities in forests and pastures, as they had a better knowledge of the population and activities of
96 wolves (Gros 1998). To foster a comfortable, non-intimidating information exchange process with
97 local residents, the interviews did not include any government staff, and we explained to local residents
98 that the interview was for scientific research purposes only (Kvale 1996).

99 During interviews, we used a semi-structured questionnaire to minimize the influence of the
100 questions on the response (Wengraf 2001). Interviews were performed orally with responses recorded
101 immediately post-interview into the standardized questionnaire. First, we recorded respondents'
102 personal characteristics, including ethnicity (a variable correlated with the religious belief system),
103 gender, age and education level (three levels: "illiterate", "elementary school", and "secondary and
104 above"). We did not ask their household incomes, because a pilot survey found it difficult to get the
105 true value from respondents. Second, we asked for information about livestock in the past three years,
106 including the annual number of livestock grazed by each family and the annual number of livestock
107 depredated by wolves. Third, we asked their opinions about wolf population trends in their areas over
108 the past 10 years ("increasing", "stable", and "decreasing"). Finally, we assessed their attitudes towards
109 wolves. We included three questions as proxy measures for attitude: (1) "What do you think of

wolves?"; (2) "What do you intend to do in response to livestock depredation by wolves?"; (3) "Do you think that wolves should be protected? If a person thought wolves were bad and detrimental, wanted to kill wolves who were attacking their livestock, and did not wish to protect wolves, we considered that the person was negative towards wolves; if the opposite were the case, we considered the person to have a positive attitude towards wolves. If a person had no strong opinion to the questions, we considered the person to have a neutral attitude towards wolves. If the respondent showed a positive attitude in response to some questions and a negative attitude in response to others, we defined this as a mixed response.

Data analysis

We first calculated descriptive statistics of responses to analyze the basic information from the interviews. We used to T-tests and Chi-squared tests of independence (Fisher's exact tests were employed if any expected frequency was below 1 or more than 20% of expected frequencies were less than 5) to compare differences of responses between two village categories, those with more frequent reports of wolf depredation and those less frequent reports of wolf depredation.

Then, we examined how people's attitudes towards wolves were affected by variables of personal characteristics (including ethnicity, age, and education level; gender was not included in the analysis because of only a few respondents were women), and by variables relating to livestock (i.e. annual number of livestock grazed and annual percentage of livestock depredated by wolves). We included all villages but used village category as an additional prediction factor. We excluded one sample with mixed opinion about our measures and pooled positive and neutral attitudes due to the small number of responses in these categories. We also excluded two samples with missing values. We conducted a binary logistic regression, where a totally negative attitude was scored as 1 while a positive or neutral attitude was scored as 0. In the regression, annual percentage of livestock depredated was considered 0 if there was no livestock grazed (note that this applied only to the

134 regression and not to the previous descriptive statistics). Categorical variables including village
135 category, ethnicity and education level were converted into a set of dichotomous, dummy-coded
136 variables. We set “villages with more frequent reports of wolf depredation” as the reference for village
137 category, “Tibetan” as the reference for ethnicity, and “illiterate” as the reference for education level.

138 We used the Akaike information criterion corrected for small sample size (AICc) to compare
139 statistical models constituting different combinations of variables. We calculated ΔAICc , which means
140 the difference between the model with the lowest AICc and the other models in the model set. The
141 model with the lowest AICc was considered as the best model, when ΔAICc between it and the next
142 best model was larger than two (Burnham & Anderson 2002). However, if there were some models
143 whose ΔAICc was ≤ 2 (which means that these models had equivalent support to explain the data), we
144 used a normal model averaging approach over all candidate models to get parameters and error
145 estimates (Burnham & Anderson 2002; Anderson 2008). We calculated the 95% confidence interval
146 (95% CI) of parameter estimate and the odds ratio (OR) of the effects for each variable. We also
147 estimated the relative importance (w_+) of a given variable by summing the Akaike weights of all
148 models containing the variable, and compared variables by examining the ratio of w_+ . Variables were
149 considered as associated statistically with the response variable, when their 95% CIs excluded the zone
150 value (Grueber et al. 2011). All analyses were performed on R 3.0.0 (R Development Core Team,
151 2013).

152

153 Results

154 In total, we interviewed 100 residents, of which 81 belonged to villages that reported wolf depredation
155 more frequently, and 19 to villages with less frequent reports of depredation. The respondents’
156 personal characteristics did not differ significantly between the two village categories (Table 1).

Overall, they averaged 44 years of age, with 36% illiterate, 44% with elementary education, and 20% with secondary or higher education. Half of the respondents were Tibetan, and the other half were Han.

During the preceding three years, most families of the respondents owned livestock that they grazed on alpine pastures. Most of them reported that their livestock suffered from depredation by wolves (Table 2). The two village categories we defined did not differ significantly in livestock ownership and percent of families experiencing depredation; however, there was a trend toward higher mean annual livestock loss rate in villages that reported depredation more frequently compared with those with less frequent reports of depredation (Table 2).

Most respondents in the more frequently depredated villages perceived an increase in wolf populations, whereas more than half of respondents in the less frequently depredated villages perceived a decrease in wolf populations in their areas (Table 3). With respect to people's attitudes towards wolves, there was no significant difference between the two village categories (Table 3). The majority of the respondents were negative in their attitude to wolves. All the people who were negative towards wolves mentioned that livestock loss caused by wolves was the main reason for their attitude. Therefore, they wanted to kill wolves and did not wish to protect them. Only very few (3.6%, 3/84) people talked about fear of wolves, and no one mentioned an event of wolves attacking humans.

We constructed 64 candidate logistic regression models with six variables, where we excluded one sample with mixed opinion towards wolves and two samples with missing values, to predict variation of people's attitudes towards wolves. As there were 13 models with $\Delta AICcs \leq 2$, we used a model averaging approach to calculate estimates for variables. The results showed that the number of livestock owned was the most important predictor, with the other five variables having lower relative importance to it (Table 4). Only the number of livestock owned was statistically related to attitudes of the respondents towards wolves, as its 95% CI of the parameter estimate excluded the zero value. People with a more negative attitude towards wolves owned larger numbers of livestock, on average

(Fig. 2). For each additional animal owned, people were, on average, 1.032 times more likely to have a negative attitude towards wolves (Table 4). Variation of attitudes towards wolves was not predicted by village category, the percentage of livestock depredated by wolves and factors associated with personal characteristics (i.e. ethnicity, age, and education level).

185

186 Discussion

Understanding the perceptions of local people living adjacent to wildlife habitats of wildlife-human interactions is important in the conservation of large carnivores, because they are apt to provide reliable information about wildlife (Treves & Karanth 2003; White et al. 2005). However, it is difficult for the public to estimate wolf population sizes (Bjerke, Reitan & Kellert 1998). In this study, we instead asked local people's opinions about wolf population trends. Similar studies have been previously conducted on other large carnivores, for example the Asiatic black bear *Ursus thibetanus* (Liu et al. 2011).

Most of the people we interviewed reported an increase in wolf populations in their areas in the preceding 10 years. The apparent increase in abundance may reflect effective protection and population recovery of the wolf in the wild since the prohibition of guns in 1996. This may have resulted in the increased livestock depredation and human-wolf conflicts as reported. Increase in human-wolf conflict may also be a result of human encroachment on wolves' natural habitats (Naughton-Treves, Grossberg & Treves 2003) and ongoing degradation or loss of habitat (Yang 2008). In this case, wolves may more frequently encounter and prey on livestock as their natural prey populations have declined.

Nevertheless, more than half of respondents in the less frequently depredated villages perceived a decrease in wolf abundance in their areas. Insights that we have gained in these villages indicate that some people illegally killed wolves in their areas. It should be noted that livestock losses were self-reported in the interviews, and the reported magnitude of losses may differ from reality. It was hard to

205 verify the magnitude of these reported losses in the present study, and thus we suggest that additional
206 research is needed on this topic.

207 As reported by some previous studies in other regions (e.g., Ericsson & Heberlein 2003;
208 Naughton-Treves, Grossberg & Treves 2003; Tuğ 2005; Røskft et al. 2007), the local population had
209 a negative attitude to wolves. Attitudes toward wolves are strongly driven by physical and behavioral
210 characteristics of wolves as well as by some cultural and historical associations such as human fear of
211 wolves (Kleiven, Bjerke & Kaltenborn 2004; Bisi et al. 2007; Suryawanshi et al. 2013). In our study,
212 the local people's explanation for negative attitude was livestock loss due to wolves, while very few
213 indicated fear of wolves. Despite widespread fear of wolves, attitudes may differ between areas and
214 groups as a result of different awareness of the biological characteristics of wolves, including
215 avoidance of humans (Bisi et al. 2007; Yang 2008).

216 However, our finding, that variation of attitudes was not explained by personal characteristics,
217 is inconsistent with previous studies in which people's attitudes towards wolves differed significantly
218 according to their age, education level and income (e.g., Ericsson & Heberlein 2003; Naughton-Treves,
219 Grossberg & Treves 2003; Tuğ 2005; Røskft et al. 2007). We found that Tibetan people were as
220 negative as Han people, and this was not expected, as Tibetan groups, being Buddhist, find it easier to
221 accept the protection of wildlife than Han people who have no dominant religion (Eckel 1998). A
222 similar result was also reported by Liu et al. (2011) in the study on human-bear conflicts of western
223 Sichuan. It is possible that increase in conflicts between wolves and the local villagers at our study area
224 might have resulted in negative public opinion. We suspect, though, that Tibetan people would be less
225 likely to attack wolves in response to livestock loss or to engage in poaching, because of their belief
226 that killing wildlife could negatively affect their resurrection in the afterlife (Eckel 1998; Liu et al.
227 2011).

228 Little research has examined the potential links between attitude and variables concerning
 229 livestock. This study revealed that people with relatively large numbers of livestock were more likely
 230 to have a negative attitude towards wolves than those with smaller numbers of livestock. To our
 231 knowledge, there is no previous literature that has reported this phenomenon. In addition, we did not
 232 find that people who had lost a larger percentage of their livestock to wolf depredation showed a more
 233 negative attitude to wolves, as concluded by some previous studies concerning the wolf conflicts
 234 (Williams, Ericsson & Heberlein 2002; Ericsson & Heberlein 2003; Naughton-Treves, Grossberg &
 235 Treves 2003; Tuğ 2005). We acknowledge that assigning zero predation to informants who had no
 236 livestock would artificially reduce the predation intensity, thus may have affected the relationship
 237 between livestock losses and attitude towards wolves. Unfortunately, because of small samples, we
 238 cannot further test the effect of percent loss using only those informants who had livestock.

239 As an explanation, we suggest that the current finding might be associated with the fact that the
 240 local people were impoverished and had seldom been compensated for their losses, while livestock
 241 mortality by wolves was a relatively common occurrence. It is expected that people who grazed a
 242 larger number of livestock and whose main source of income was from livestock, would be negative
 243 towards anything that may cause loss of their livestock and threaten their income. Even if wolves had
 244 not killed their livestock in the past, they would still have a negative attitude to wolves as they felt that
 245 no one could guarantee the safety of their livestock in the future. In contrast, people with a smaller
 246 number of livestock would expected to be neutral or positive in their attitude to wolves, as usually they
 247 were able to obtain income from other sources and the economic benefits from livestock accounted
 248 only for a small part of their incomes.

249

250 Management implications

251 To mitigate future human-wolf conflicts, we must reduce livestock losses of local people who
 252 suffer from wolf depredation. In our study site and related areas, a large livestock group is herded
 253 commonly by a couple of people. Younger people are not willing to take up this lifestyle. Furthermore,
 254 existing corrals are poorly built. Ineffective guarding of livestock might have facilitated depredation by
 255 wolves (Jackson 2000; Treves & Karanth 2003; Li et al. 2013). Therefore, we suggest that the best
 256 approach at present should be to improve guarding of livestock in the context of local cultures and
 257 conditions, for example, increasing the number of herders, developing expertise in herding, and
 258 building wolf-proof corrals using local materials (see Namgail, Fox & Bhatnagar 2007).

259 Eco-compensation in mitigating human-wildlife conflicts has been increasingly emphasized by
 260 the government in recent several years (Xinhuanet 2014; Yunnan.cn 2014). Public education on wolf
 261 conservation has been conducted in our study area, but there has been no any provision of monetary
 262 compensation for herders who lost livestock to wolves. The local forestry department mentioned many
 263 obstacles, such as the difficulty of verifying the magnitude of livestock losses reported by local
 264 villagers. As an alternative approach, we could invest these monies in human resources and
 265 infrastructure, such as training herders and improving corrals. This will distribute the benefit equitably
 266 (Namgail, Fox & Bhatnagar 2007). Furthermore, initiation of a livestock insurance program guided by
 267 the government, a measure that has proved effective in the India's Trans-Himalayan region (Mishra et
 268 al. 2003), is encouraged for a long-term management.

269 There are other alternatives such as relocation or limited removal of problem wolves (e.g.,
 270 Mech & Boitani 2003; Treves & Karanth 2003; Bradley et al. 2005), and change of local livelihood
 271 (e.g., Jackson 2000; Conforti & de Azevedo 2003; Li et al. 2013). The local government is considering
 272 employing armed police to kill problem wolves. Although a reported increase in the wolf populations
 273 and in livestock depredation by wolves in our study area, causal relationships between them are not
 274 clear. In addition, there is no scientific information on wolf population sizes. Therefore, this measure

will require further data on wolf population sizes and their relations with livestock depredation. The local government is also assisting herders to attempt to increase incomes from alternative sources, for example eco-tourism and the cultivation of economically important alpine plants, aiming to reduce their dependency on livestock. Two of the 12 villages we interviewed seemed to have been moving toward a more positive attitude towards wolves. However, it should be noted that local people might resist directions from authorities. Shift to other areas may also have different environmental impacts. The forms of income generation should be implemented and sustained selectively through existing institutions (Jackson 2000).

283

284 Conclusions

To conclude, this study investigated local villagers' perceptions of wolves in Jiuzhaigou County, western China. Most people, especially in villages with more frequent reports of wolf depredation to the local government, reported an increase of wolf population and thus increased livestock losses to wolves. People were generally negative towards wolves, despite a prevalent Tibetan culture that favors the protection of wildlife. These with a larger number of livestock were more likely to have a negative attitude towards wolves. In term of conservation management, we suggest that improved guarding of livestock and provision of monetary support on human resources and infrastructure may mitigate human-wolf conflicts in this region. Our study provides insights into management of human-wolf conflicts in western China.

Table 1(on next page)

Comparison of respondents' personal characteristics between villages with more frequent reports of wolf depredation and those with less frequent reports of wolf depredation

Village category	Mean age (range)	Proportion of ethnic groups		Proportion of education levels		
		Tibetan	Han	Illiterate	Elementary school	Secondary and above
Villages with more frequent reports of depredation (n = 9 villages, and 81 respondents)	44 (16-81)	49.4% (40/81)	50.6% (41/81)	34.6% (28/81)	45.7% (37/81)	19.8% (16/81)
Villages with less frequent reports of depredation (n = 3 villages, and 19 respondents)	46 (23-77)	52.6% (10/19)	47.4% (9/19)	42.1% (8/19)	36.8% (7/19)	21.1% (4/19)
Statistical tests	t = -0.536, df = 98, P = 0.593	$\chi^2 = 0.065$, df = 1, P = 0.799		$\chi^2 = 0.529$, df = 2, P = 0.768		

Table 2(on next page)

Comparison of estimates of livestock ownership and livestock depredation between villages with more frequent reports of wolf depredation and those with less frequent reports of wolf depredation

Village category	Percentage of families with livestock grazed	Average annual number of livestock owned per family (range)	Percentage of families with livestock depredated by wolves	The reported annual livestock loss rate to wolves (range)
Villages with more frequent reports of depredation (n = 9 villages, and 81 respondents ^a)	86.3% (69/80)	41 (4-200)	82.6% (57/68)	21.7% (0-70%)
Villages with less frequent reports of depredation (n = 3 villages, and 19 respondents)	73.6% (14/19)	53 (3-200)	64.3% (9/14)	11.7% (0-30%)
Statistical tests	Fisher's exact test P = 0.184	t = -0.981, df = 81, P = 0.330	Fisher's exact test P = 0.134	t = 1.180, df = 80, P = 0.074

- 2 ^a no data values were recorded for livestock ownership and livestock depredation in one sample, and there is one missing value for livestock
- 3 depredation in another sample.

Table 3(on next page)

Comparison of respondents' opinions about wolf population trends and attitudes towards wolves between villages with more frequent reports of wolf depredation and those with less frequent reports of wolf depredation

Village category	Proportion of opinions about wolf population trends			Proportion of attitudes towards wolves			
	Increasing	Decreasing	Stable	Negative	Positive	Neutral	Mixed
Villages with more frequent reports of depredation (n = 9 villages, and 81 respondents)	79.0% (64/81)	16.0 % (13/81)	4.9% (4/81)	86.4% (70/81)	7.4% (6/81)	4.9% (4/81)	1.2% (1/81)
Villages with less frequent reports of depredation (n = 3 villages, and 19 respondents)	47.4% (9/19)	52.6% (10/19)	0 (0/19)	73.7% (14/19)	26.3% (5/19)	0 (0/19)	0 (0/19)
Statistical tests	Fisher's exact test P = 0.005			Fisher's exact test P = 0.116			

Table 4(on next page)

Model-averaged coefficients and relative importance calculated for variables explaining variation in attitude of respondents towards wolves

Variable	Estimate	SE	Lower 95% CI	Upper 95% CI	OR	z value	wi ₊
Intercept	0.175	1.115	-2.010	2.360	1.191	0.156	
ANL	0.032	0.016	0.001	0.062	1.032	2.018	0.93
Ethnicity_Han ^a	1.082	0.747	-0.382	2.546	2.951	1.432	0.53
Village category_less frequent reports of wolf depredation ^b	-0.945	0.687	-2.293	0.402	0.389	1.358	0.46
APL	2.144	1.806	-1.395	5.683	8.534	1.173	0.44
Age	0.025	0.024	-0.022	0.072	1.025	1.038	0.38
Education level_secondary and above ^c	0.370	0.870	-1.335	2.075	1.447	0.42	0.32
Education level_elementary school	0.599	0.674	-0.721	1.920	1.821	0.878	-

2 ^a “Tibetan” was the reference category

3 ^b “Villages with more frequent reports of wolf depredation” was the reference category

4 ^c “Illiterate” was the reference category

5 Abbreviations: ANL, annual number of livestock the respondent’s family grazed; APL, annual percentage of livestock depredated by wolves;

6 OR, the odds ratio.

1

Map showing the study area, Jiuzhaigou County, Sichuan Province, western China, as well as locations of villages investigated in the study

The dark circles represent villages with more frequent reports of wolf depredation, and the dark squares villages with less frequent reports of wolf depredation

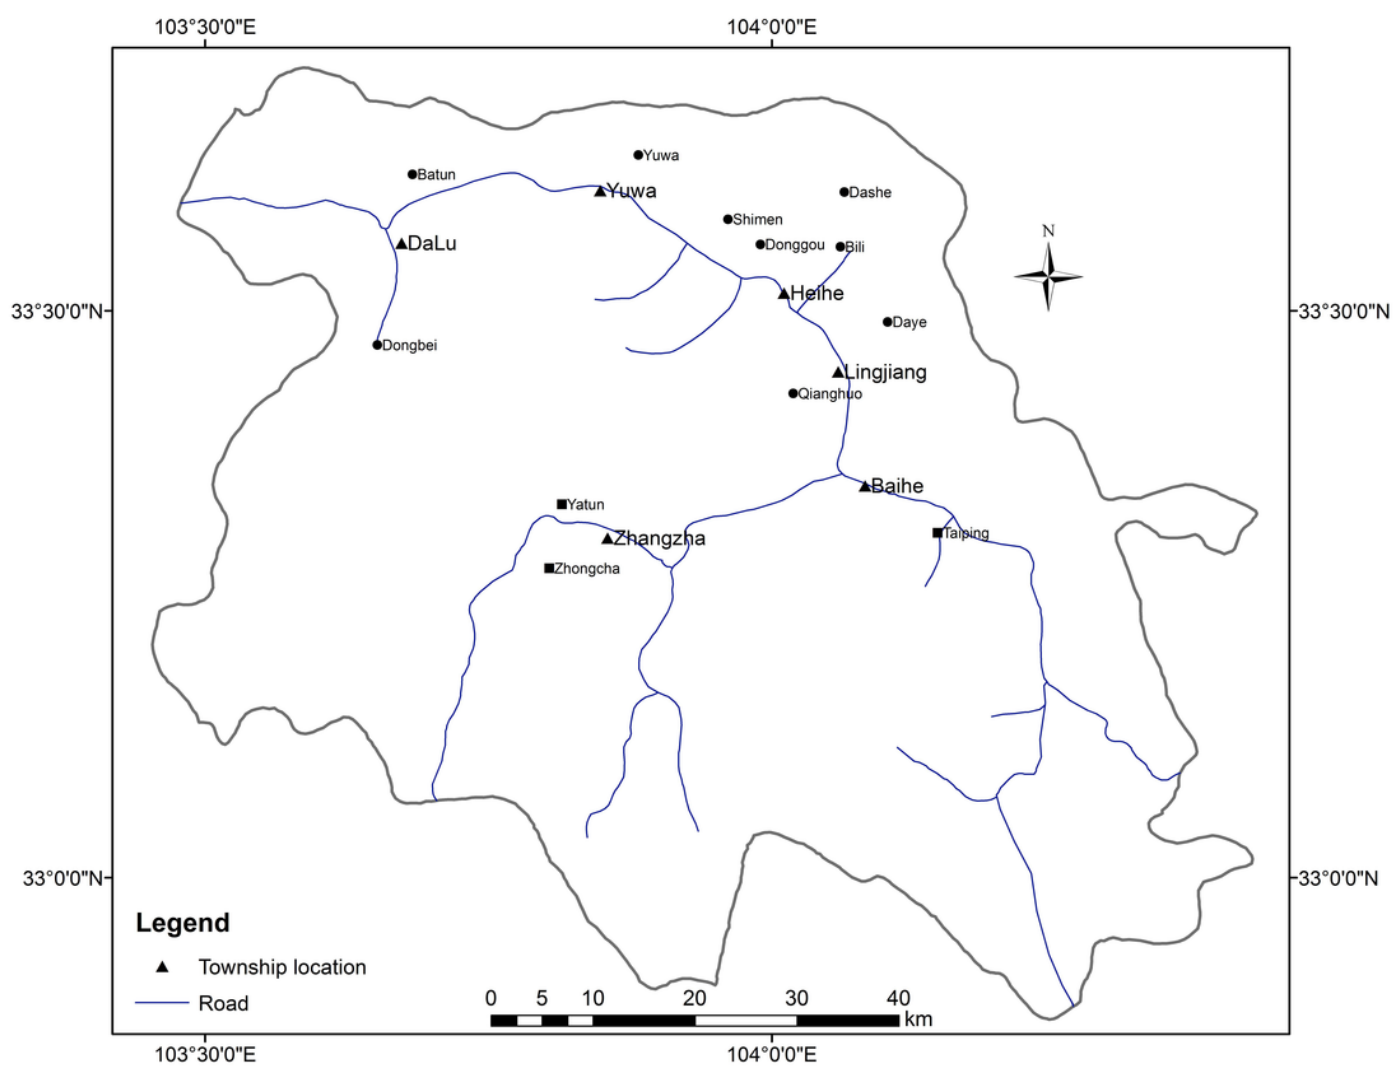

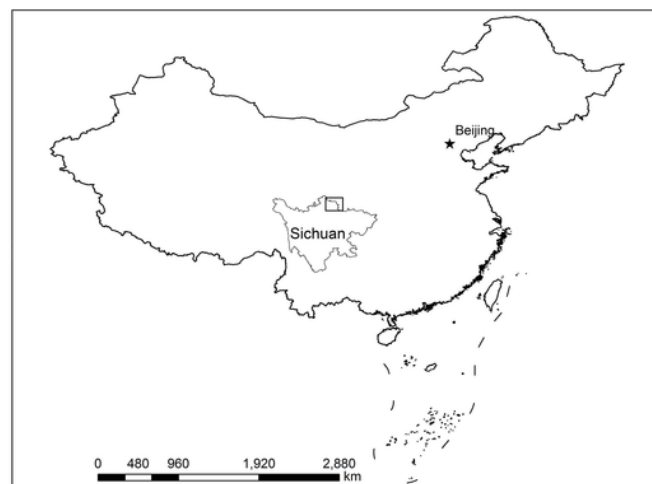

Figure 2(on next page)

Mean annual number of livestock \pm 1 SE grazed by families of respondents who had different attitudes towards wolves
