Oligodeoxynucleotides (ODNs) are typically purified and analysed with HPLC equipped with a UV-Vis detector. Quantities of ODNs are usually determined using a UV-Vis spectrometer separately after HPLC, and are reported as optical density at 260 nm (OD_{260}). Here, we describe a method for direct determination of OD_{260} of ODNs using the area of the peaks in HPLC profiles. It is expected that the method will save significant time for researchers in the area of nucleic acid research, and minimize the loss of oligonucleotide samples.

Determination of optical density (OD) of oligodeoxynucleotide from HPLC peak area

Abstract: Oligodeoxynucleotides (ODNs) are typically purified and analysed with HPLC equipped with a UV-Vis detector. Quantities of ODNs are usually determined using a UV-Vis spectrometer separately after HPLC, and are reported as optical density at 260 nm (OD_{260}). Here, we describe a method for direct determination of OD_{260} of ODNs using the area of the peaks in HPLC profiles. It is expected that the method will save significant time for researchers in the area of nucleic acid research, and minimize the loss of oligonucleotide samples.

Keywords: HPLC; OD; oligonucleotide; optical density; quantification

Introduction

Oligodeoxynucleotides (ODNs) synthesized on an automated synthesizer are usually purified using reversed-phase (RP) or ion-exchange HPLC.[1-2] Their purity is also usually determined using HPLC. For both preparative and analytical HPLC, the elution profile is mostly generated using a UV-Vis detector with the wavelength set to 260 nm. Quantities of ODNs are typically documented using optical density at 260 nm, which is abbreviated as OD_{260}. It is defined as the UV absorbance at 260 nm (A_{260}) of the ODN to be quantified dissolved in 1 mL of water with a light path of 1 centimetre. The value of OD_{260} is usually determined separately after an ODN is purified by HPLC using an UV spectrometer or other UV based apparatus such as a NanoDrop. Because the peak area in an HPLC profile is a quantitative measure of the UV absorbance of the ODN eluted within the peak, we reasoned that a separate step for the determination of OD_{260} using a UV spectrometer as we usually do is unnecessary, and the OD_{260} value can be determined directly using the peak area in the HPLC profile. Here, we describe the establishment of a correlation curve between HPLC peak areas and OD_{260} values and demonstrate its use for the determination of OD_{260} using HPLC peak area without having to measure UV absorbance separately.

Materials and Methods

Oligodeoxynucleotides (ODN) **1a** (20-mer, 5'- TCA TTG CTG CTT AGA CCG CT-3'),

35   **1b** (21-mer, 5'-TTG CCA TGA TTG ACA ACC AAT-3') and **1c** (32-mer, 5'-TAG TTT TAT AAT
36   TTC ATC AGC AGT GTT ACC GT-3') were either obtained from a commercial source or
37   synthesized on a MerMade-6 DNA/RNA synthesizer at 1 (**1a**) or 0.2 (**1b-c**) µmol scale under
38   standard synthesis, cleavage and deprotection conditions.[3] RP HPLC was carried out under
39   typical conditions described elsewhere.[4] UV absorbance was obtained on a Horiba Scientific
40   Duetta Fluorescence and Absorbance Spectrometer at 260 nm in a 1 mL quartz cuvette with a 1
41   cm light path. Water was used as the blank.

42   For establishing the correlation curve of OD_{260} vs HPLC peak area (Figure 1, see
43   supporting information for a protocol for establishing the curve), ODN **1a**, which was synthesized
44   at 1 µmol scale and purified with trityl-on RP HPLC, was dissolved in 1 mL water. Different
45   volumes of the solution (see Table 1) were injected into HPLC. For each injection, the peak area
46   of the ODN was recorded, and the fractions corresponding to the peak were collected, combined
47   and concentrated to dryness in a centrifuge evaporator under vacuum. The ODN was dissolved in
48   1 mL water. UV absorbance at 260 nm, which is the OD_{260} of the ODN in the corresponding HPLC
49   peak, was obtained on a UV-Vis spectrometer using the solution in a 1 mL cuvette with a 1 cm
50   light path (Table 1). The correlation curve of the values of OD_{260} vs the HPLC peak areas for the
51   injections were generated and presented in Figure 1. The slopes of the line is 0.00033.

52   To demonstrate the use of the curve for the determination of OD_{260} from HPLC peak area,
53   ODN **1b** was synthesized at 0.2 µmol scale on CPG, cleaved, deprotected, and purified with trityl-
54   on RP HPLC. One twentieth of the ODN was injected into HPLC. The area of the ODN peak was
55   found to be 498.3, which corresponds to an OD_{260} of 0.164 according to the line obtained using
56   the UV-Vis spectrometer in Figure 1. Thus, the OD_{260} for the 0.2 µmol ODN synthesis was 3.29.
57   To validate the result, the OD_{260} of the synthesis was also determined using standard method by
58   measuring the absorbance at 260 nm on a UV-Vis spectrometer. The number obtained was 3.31.
59   The use of the curve was further validated using ODN **1c** following the same procedure for **1b**.
60   The OD_{260} values calculated from the line obtained using the UV-Vis spectrometer and obtained
61   a UV-Vis spectrometer were 7.42 and 7.10, respectively.

Results and Discussion

63   Oligonucleotides including oligodeoxynucleotides (ODN) are usually quantified by
64   measuring UV absorbance at 260 nm (OD_{260}) in a separate step after HPLC purification or analysis.
65   Once the value of OD_{260} of an oligonucleotide is obtained, its mass in micro grams or micro moles
66   can be easily calculated based on its sequence. Such calculations are usually carried out using free
67   online tools by simply imputing the sequence and the OD_{260} value. In this report, we describe a
68   method to determine OD_{260} directly from the area of HPLC peak instead of obtaining the value in
69   a separate step.

70   To use HPLC peak area to determine OD_{260}, a correlation curve between OD_{260} and HPLC
71   peak area needs to be established first (see supporting information for a protocol). ODN **1a** is used
72   to demonstrate the process. A solution of **1a** from a 1 µmol synthesis was prepared (see Materials

73 and Methods section). The concentration does not need to be known or accurate, but should be
74 suitable for the generation of HPLC peaks with areas close to those in HPLC profiles a lab typically
75 generates for ODN purification and analysis. For the case of **1a**, the ODN from the 1 µmol
76 synthesis was dissolved in 1 mL water. Various volumes as indicated in Table 1 were injected into
77 HPLC. For each injection, the ODN under the correct peak was collected and the area of the same
78 peak was recorded (Table 1). The ODN was evaporated to dryness, and dissolved in 1 mL of water.
79 The value of OD_{260} was then obtained by measuring the absorbance using a UV spectrometer.
80 Plotting the OD_{260} numbers against peak areas gave the required correlation curve (Figure 1). As
81 expected, the data fitted well with straight line with a slope of 0.00033.

82 Once the correlation curve is obtained, the OD_{260} for any ODN that has an HPLC profile
83 can be easily calculated. The ODN **1b**, which was synthesized at a 0.2 µmol scale, is used as an
84 example. One twentieth of the crude ODN was injected into HPLC. The area of the ODN peak
85 was found to be 498.3. Using the correlation line generated with the data from UV-Vis
86 spectrometer in Figure 1, the area corresponds to an OD_{260} of 0.164. Alternatively, the OD_{260} can
87 be simply calculated using the slope of the line, which gave the same number (498.3 × 0.00033).
88 With the number for a portion of the sample, the OD_{260} for the 0.2 µmol synthesis can be easily
89 calculated, which is 3.29 (0.1644 × 20). To validate the result, the OD_{260} of the synthesis was
90 measured in a standard way using a UV-Vis spectrometer, and the value was 3.31, which was close
91 to the value calculated from the graph or the slope. The method was further validated using ODN
92 **1c** using the same procedure for **1b**, and the numbers from the graph and from standard
93 measurement were 7.10 and 7.42, respectively.

94 Although the method for the determination of OD_{260} is simple and convenient, it is
95 recommended that the validity of the standard curve or slope is checked whenever the HPLC
96 conditions such as column, eluents, gradient, flow rate and temperature are changed. In addition,
97 if the flow cell of the UV detector is replaced or cleaned, a new curve should be generated.
98 Gratifyingly, in most labs, HPLC is typically performed under consistent conditions and UV
99 detector flow cell can last for many years, there is no need to validate the graph frequently. Another
100 suggestion is that when the area of the peak of an ODN is out of the areas used to generate the
101 correlation graph, caution is needed to use the graph to calculate its OD_{260} because the correlation
102 may not be linear when the concentration of the ODN in the eluent is too high. We suggest only
103 use HPLC peak area to determine OD_{260} when the concentration of the eluent is not too high and
104 is within the linear curve range. Finally, it is important to point out that the usually long and thick
105 waste eluent line connecting the UV detector flow cell to waste container needs to be removed
106 when collecting fractions of eluent to generate the OD_{260}-HPLC peak area correlation graph. If
107 this were not followed, the fractions collected may not be the fractions corresponding to the
108 intended HPLC peak.

Conclusion

110 In summary, a simple and convenient method for the determination of OD_{260} of
111 oligonucleotides using HPLC peak area is described. Although only quantification of ODN is

112 described here, it is conceivable that the method can be equally applicable to RNA quantification.
113 Because synthetic oligonucleotides typically have to go through the HPLC procedure for the
114 purposes of purification or analysis, the direct OD_{260} determination method can save time for
115 researchers by bypassing the step of measuring UV absorbance using a spectrometer.

HPLC peak areas and their corresponding OD_{260} values.[a]

[a] The ODN **1a** synthesized at 1 µmol scale was purified with trityl-on HPLC, and dissolved in 1 mL water. Different volumes were injected into HPLC. The peak areas were recorded, and the fractions corresponding to the peak areas were collected. The fractions were evaporated to dryness and dissolved in 1 mL water. The values of UV absorbance at 260 nm (OD_{260}) were then obtained in a 1 mL cuvette with a 1 cm light path. The listed values were the average of three measurements.

1 **Table 1.** HPLC peak areas and their corresponding OD_{260} values.[a]

Entry	Volume (μL)	HPLC peak area	OD_{260}
1	4.0	485.0	0.176
2	6.0	781.3	0.269
3	9.0	1113.1	0.395
4	12.0	1497.6	0.496
5	15.0	1925.1	0.616
6	20.0	2408.3	0.778

4 [a] The ODN **1a** synthesized at 1 μmol scale was purified with trityl-on HPLC, and dissolved in 1
5 mL water. Different volumes were injected into HPLC. The peak areas were recorded, and the
6 fractions corresponding to the peak areas were collected. The fractions were evaporated to
7 dryness and dissolved in 1 mL water. The values of UV absorbance at 260 nm (OD_{260}) were then
8 obtained in a 1 mL cuvette with a 1 cm light path. The listed values were the average of three
9 measurements.
