A precise analytical method was established for rapid screening of 49 antibiotic residues in aquatic products by ultra-high performance liquid chromatography-quadrupole time of flight mass spectrometry (UPLC-QToFMS). The quick, easy, cheap, effective, rugged and safe (QuEChERS) process was refined for effective sample preparation. The homogenized samples of aquatic products were extracted with 3% acetic acid in acetonitrile, salted out with anhydrous magnesium sulfate and sodium chloride, and cleaned up by octadecylsilane (C18) and primary-secondary amine (PSA) powder. Then, the purified samples were separated on a BEH C18 column using 0.1% formic acid and methanol as mobile phases by gradient elution, detected by MS under positive Electron Spray Ionization (ESI+) mode. The linear range of matrix-matched calibration curve was 1-100 µg/L for each compound with the correlation coefficients in the range of 0.9851-0.9999. The recoveries of target antibiotics at the different spiked levels ranged from 60.2% to 117.9% except for lincomycin hydrochloride, whereas relative standard deviations (RSDs) were between 1.6% and 14.0% except for sulfaguanidine in grass Carp, *Penaeus vannamei* and *Scylla serrata* matrices. The limits of detection (LODs) (S/N=3) for the analytes were 0.05-2.40 µg/kg, 0.08-2.00 µg/kg and 0.10-2.27 µg/kg and the limits of quantification (LOQs) (S/N=10) were 0.16-8.00 µg/kg, 0.25-6.66 µg/kg and 0.32-7.56 µg/kg in grass Carp, *Penaeus vannamei* and *Scylla serrata*, respectively. The method was successfully applied to grass Carp, *Penaeus vannamei* and *Scylla serrata*, demonstrating its ability for the determination of multi-categories antibiotic residues in aquatic products.

10 **Abstract** A precise analytical method was established for rapid screening of 49 antibiotic residues in aquatic
11 products by ultra-high performance liquid chromatography-quadrupole time of flight mass spectrometry
12 (UPLC-QToFMS). The quick, easy, cheap, effective, rugged and safe (QuEChERS) process was refined for
13 effective sample preparation. The homogenized samples of aquatic products were extracted with 3% acetic
14 acid in acetonitrile, salted out with anhydrous magnesium sulfate and sodium chloride, and cleaned up by
15 octadecylsilane (C18) and primary-secondary amine (PSA) powder. Then, the purified samples were separated
16 on a BEH C18 column using 0.1% formic acid and methanol as mobile phases by gradient elution, detected by
17 MS under positive Electron Spray Ionization (ESI+) mode. The linear range of matrix-matched calibration
18 curve was 1-100 µg/L for each compound with the correlation coefficients in the range of 0.9851-0.9999. The
19 recoveries of target antibiotics at the different spiked levels ranged from 60.2% to 117.9% except for
20 lincomycin hydrochloride, whereas relative standard deviations (RSDs) were between 1.6% and 14.0% except
21 for sulfaguanidine in grass Carp, *Penaeus vannamei* and *Scylla serrata* matrices. The limits of detection
22 (LODs) (S/N=3) for the analytes were 0.05-2.40 µg/kg, 0.08-2.00 µg/kg and 0.10-2.27 µg/kg and the
23 limits of quantification (LOQs) (S/N=10) were 0.16-8.00 µg/kg, 0.25-6.66 µg/kg and 0.32-7.56 µg/kg in
24 grass Carp, *Penaeus vannamei* and *Scylla serrata*, respectively. The method was successfully applied to
25 grass Carp, *Penaeus vannamei* and *Scylla serrata*, demonstrating its ability for the determination of multi-

26 categories antibiotic residues in aquatic products.

27

28 **1. Introduction**

29 Antibiotics, as a vital medicine with bactericidal or bacteriostatic effect, are widely used in modern
30 aquaculture to prevent infectious diseases and promote growth for the increase of aquatic
31 production(LiuWuZhangLvXu & Yan 2018; LiuSteele & Meng 2017). However, antibiotics would be a
32 dietary risk in cultured aquatic products with abuse of antibiotics happened. Their residues may directly enter
33 the human body and accumulate in human organs. Therefore, they could lead to a series of adverse reactions
34 and toxicological effects, such as allergic reactions, toxic reactions, liver damage, kidney damage, nervous
35 system damage, and so on(MoChenLeung & Leung 2017). More seriously, the extensive usage of antibiotics
36 could induce antimicrobial resistance which is considered as a public health
37 threat(AndersonJenkinsEvansHarrisWeinsteinTammaHanBanerjeePatelZaoutis & Lautenbach 2017). Based on
38 both major negative effects above, regulatory limits for veterinary medicine residues are worldwide issued by
39 many countries and organizations like Ministry of Agriculture (MOA) of China No 235 and European Union
40 (EU) No 37/2010(DelatourRacaultBessaire & Desmarchelier 2018). To protect consumers, the overall situation
41 of antibiotic residues in aquatic products that serve as a main food source in coastal areas of China has gained
42 increasing attention from governments.

43 At present, the analytical methods for antibiotics in animal food mainly include liquid chromatography
44 (LC)(ZhouWangZhu & Tang 2015), liquid chromatography tandem triple quadrupole mass spectrometry (LC-
45 MS/MS)(GuidiSantosRibeiroFernandesSilva & Gloria 2018) and liquid chromatography hybrid quadrupole
46 time-of-flight mass spectrometry (LC-QToFMS)(KiHurKimKimMoonOh & Hong 2019). An LC method is
47 always equipped with fluorescence detector which has the disadvantage of lower sensitivity and poorer
48 qualitative ability. The major shortcoming of LC-MS/MS is a limited throughput when each compound needs
49 optimization in instrumental parameter of mass spectrometer. With the significant advances in the performance
50 of LC-QToFMS, this platform has the outstanding merits of high resolution, high sensitivity and applicability
51 for high throughput screening analysis in aquatic products(GuChengZhenChen & Zhou 2019) . Owing to its
52 excellent characteristics, hereby an ultra performance LC-QToFMS (UPLC-QTOFMS) was applied for the

53 rapid determination of multi-categories antibiotic residues at levels below their general maximum residue
54 limits (MRLs) (2-200 $\mu\text{g}/\text{kg}$) as newly set by MOA (GB 31650-2019).

55 The quick, easy, cheap, effective, rugged and safe (QuEChERS) method introduced to improve extraction
56 efficiency and to elevate method reliability in a great variety of samples, has been significantly developed and
57 successfully applied in the residues analytical field (Garcia & Gotah 2017; Serra-CompteÁlvarez-
58 MuñozRodríguez-Mozaz & Barceló 2017). To our knowledge, previous researchers always focused on one
59 sample type or a single class of veterinary drugs. Villar-Pulido et al. established a fast QuEChERS-LC-ToFMS
60 method to detect 13 drug residues in shrimps (Villar-PulidoGilbert-LópezGarcía-ReyesMartos & Molina-Díaz
61 2011). Zhang et al. used a QuEChERS procedure without solid-phase extraction step for rapid quantification of
62 90 kinds of veterinary drugs in royal jell (ZhangLiuLiZhangCaoSuShi & Sun 2016). In this study, several kinds
63 of aquatic products were continuously analyzed where efficiently extract multi-residues from the complex
64 matrices is the most tough and trouble step. Therefore, development of a rapid, sensitive and simultaneous
65 analytical method aiming at antibiotic residues at trace levels in aquatic products is urgent.

66 **2. Materials and methods**

67 **2.1 Chemicals and solutions**

68 A total of 49 antibiotics selected for the study contains 4 families including lincosamides (2), macrolides
69 (9), quinolones (16) and sulfonamides (22) (Table 1). Forty-nine antibiotic standards and six internal isotope
70 standards (roxiyromycin-D7, enrofloxacin-D5 hydrochloride, sulfadoxine-D3, ciprofloxacin-D8, norfloxacin-
71 D5, and sulfadimethoxine-D6, purity: $>93.6\%$) were obtained from Dr. Ehrenstorfer GmbH (Germany).
72 Methanol, acetonitrile, ethyl acetate were purchased from Merck (UPLC-grade, Germany). Anhydrous sodium
73 sulfate of analytical reagent grade and HPLC-grade formic acid, acetic acid, sodium chloride, octadecylsilane
74 (C18), alumina-N (ALU-N), primary-secondary amine (PSA) and leucine enkephalin was provided by ANPEL
75 (China).

76 Individual stock solutions (100 $\mu\text{g}/\text{mL}$) were prepared by dissolving each antibiotic standard in methanol
77 and then stored at -18°C . Mixed standard solution (1 $\mu\text{g}/\text{mL}$) were diluted from the stock solutions with
78 methanol. Calibration curves were obtained by diluting mixed standard solution with acetonitrile - water
79 solvent (25:75 v/v) at the final concentration of 1, 5, 10, 25, 50, 100 ng/mL. The concentrations of 6 isotope

80 internal standards in each calibration standard solution were 20 ng/mL.

81 **2.2 Sample treatment**

82 Three main species of aquatic products including grass Carp, *Penaeus vannamei* and *Scylla serrata*, which
83 acted as common food in Fujian province were involved in this research. After collection from supermarkets,
84 32 fresh samples of aquatic products were treated according to Practice of sampling plans for aquatic products
85 (GB/T 30891-2014) including amount, size, transport and storage of sampling. To prevent antibiotic
86 degradation, they were immediately stored in the refrigerator at -20 °C prior to analysis. Each kind of aquatic
87 samples (2 ± 0.01 g) was thawed at room temperature and weighed into a 50 mL centrifuge tube. Afterwards,
88 each tube was added with 50 μ L mixed antibiotic standard solution (1 μ g/mL) and then was mixed and placed
89 for 15 min.

90 **2.3 Antibiotic extraction and clean-up optimization**

91 The targeted residues were extracted using a modified QuEChERS method, which were optimized in
92 terms of extractants, salting-out agents and sorbents. Antibiotics were extracted by 10 mL ACN with 3% acetic
93 acid. Then, salting-out agent (3 g of anhydrous Na_2SO_4 and 1 g of NaCl) were successively placed into the
94 tube and swirled for 1 min. Subsequently, the tube was centrifuged for 5 min at 10,000 rpm 4 °C. A 6.5 mL
95 supernatant was transferred to a 15 mL centrifuge tube containing the sorbents of 200 mg C18 and 50 mg PSA.
96 The tube was swirled for 2 min and then centrifuged for 10 min at 5,000 rpm 4 °C. Five milliliters aliquot of
97 supernatant was pipetted to a 25-mL evaporation flask and dried using a rotary evaporator under a nitrogen
98 flow at 50 °C. The residue was fully resuspended in 1 mL of acetonitrile-water solvent (25:75 v/v) by
99 ultrasonication and oscillation. The solution was subsequently filtered through 0.22 μ m nylon membrane
100 before final placement into an auto-sampler vial for the UPLC-QTOF-MS analysis.

101 **2.3 Instrumental conditions**

102 **2.3.1 Instrumental**

103 ACQUITY H-CLASS UPLC and Xevo G2-S Q-ToF mass spectrometer (Waters, USA) with electrospray
104 ionization source were used. A 3-30K high speed refrigerated centrifuge (SIGMA, USA), MS3 digital vortex
105 mixer (IKA, Germany), laborata 4000 efficient rotary evaporator (Heidolph, Germany), multi Reax oscillator
106 (Heidolph, Germany), N-EVAP™ 112 (Organomation Associates, USA) and Milli-Q water purification

107 system (Millipore, USA) were used for sample preparation.

108 **2.3.2 LC conditions**

109 The separation of mixed antibiotic standard solutions were achieved on a Waters Acquity UPLC BEH
110 C18 silica column (100 mm×3.0 mm, 1.7 μm). A gradient LC elution method was employed by 0.1% formic
111 acid aqueous solution as mobile phase A and methanol as mobile phase B.

112 The gradient elution was as follows: 10% B at 0-3 min, 10-100% B at 3-15 min, 100% B at 15-18 min,
113 100-10% B at 18-18.1min and 10% B at 18.1-21min. The injection volume, flow rate, sample manager and
114 column temperature were set at 10 μL, 0.3 mL/min, 10 °C and 40 °C, respectively. All target antibiotics were
115 eluted, and the column was cleaned and equilibrated.

116 **2.3.3 MS conditions**

117 MS experiments were operated using electrospray ionization (ESI) in the positive mode. The optimum
118 MS parameters were as follows: mass collection range 50-1000 Da; capillary voltage 3.0 kV; ion source
119 temperature 120 °C; desolvation temperature 450°C; cone gas flow 50 L/h; desolvation gas flow rate 800 L/h
120 and core voltage 40 V.

121 QToFMS screening for 49 antibiotic residues was performed using MS^E mode. The simultaneous
122 acquisition of accurate-mass full-spectrum at low and high collision energy are allowed in MS^E mode, where
123 the low collision energy (LE) spectrum provides useful information on the parent molecules and the main
124 fragment ions were obtained commonly in the high collision energy (HE) function. In this study, LE was set
125 as 6 V and HE was set from 10 eV to 40 eV. Leucine enkephalin, a commonly used peptide, was employed
126 here as a reference material to tune MS instruments in every 10 s.

127 **3.Results and discussion**

128 **3.1 Optimization of LC condition**

129 The effect of the two types of mobile phases in the separation process were compared between 0.1%
130 formic acid-acetonitrile and 0.1% formic acid water-methanol. As shown in Figure 1, using 0.1% formic acid
131 water-acetonitrile as the mobile phases, it is difficult to separate sulfamonomethoxine and
132 sulfamethoxy-pyridazine completely. It was found that when methanol was used, better resolution and higher
133 overall signal response were obtained. Therefore, 0.1% formic acid water-methanol was selected as the mobile

134 phase in this experiment.

135 **3.2 Optimization of the QuEChERS process**

136 **3.2.1 Sample extraction**

137 For the purpose of optimizing extraction of the antibiotic residues for different substrates of aquatic
138 products including grass Carp, *Penaeus vannamei* and *Scylla serrata*, ethyl acetate and acetonitrile mixed with
139 different amounts of acetic acid were compared. As shown in Fig.2, 3% acetic acid acetonitrile was used as the
140 extractant, and the average recoveries of 49 antibiotics in three matrices were 75.3%, 76.7%, 81.8%,
141 respectively, which were higher than using 1% acetic acid-acetonitrile (v:v), 5% acetic acid-acetonitrile (v:v),
142 and ethyl acetate for the extraction. Intriguingly the acidity of the extractant has a great effect on the
143 quinolones. The sequence of recoveries of quinolones from low to high was ethyl acetate, acetonitrile, 1%
144 acetic acid acetonitrile, 3% acetic acid acetonitrile, 5% acetic acid acetonitrile when each of them was
145 performed as the extractant. The possible reason is that quinolones, which are amphoteric, are easily soluble in
146 acidic or alkaline such as acetic acid solutions. From these results, 3% acetic acid acetonitrile was chosen as
147 the optimum composition of solvents for the extraction buffer.

148 **3.2.2 Purification procedure**

149 Five most commonly used sorbents were investigated in this experiment, including PSA, C18, ALU-N,
150 PSA-C18 mixture, PSA-ALU-N mixture. The purification effects on grass Carp, *Penaeus vannamei* and *Scylla*
151 *serrata* were shown in Fig.3. It is obvious that ALU-N gets an inferior purification effect probably because
152 ALU-N has a certain adsorption effect on antibiotics especially quinolones. The highest average recoveries of
153 all 49 antibiotics in three matrices were achieved using PSA-C18, overall.

154 Afterwards, the amounts of salting-out agents (anhydrous Na_2SO_4 and NaCl) and sorbents (PSA and C18)
155 were optimized using $L_9(3^4)$ orthogonal experimental design at three levels (Table 2). The results indicated that
156 satisfactory recoveries of 49 antibiotics were observed when 3g Na_2SO_4 /1 g NaCl and 50 mg PSA/200 mg C18
157 were conducted.

158 After optimization, the average recoveries of 49 antibiotics in grass Carp, *Penaeus vannamei* and *Scylla*
159 *serrata* reached 83.4%, 88.4%, and 88.8% respectively, while this procedure provided the best results for the
160 majority of target antibiotics. In summary, this improved QuEChERS process for antibiotic extraction in

161 aquatic products is fast, effective, economical and eco-friendly.

162 3.3 Method validation

163 3.3.1 Identification

164 As listed in Table 1, each of the 49 target antibiotics was measured in MS^E mode by one precursor ion
165 and at least two product ions. Meanwhile, retention time was also required to provide vital information to
166 identify specific antibiotics.

167 3.3.2 Linear range, regression equation, limits of detection and limits of quantitation

168 The series of solvent-based standard solutions were prepared according to section 2.1 and were then
169 determined by UPLC-QToFMS. The calibration curves were obtained from the relationship between the
170 analyte concentration (X, µg/L) and the analyte peak areas/internal standard peak area, providing the linear
171 equation and the correlation coefficient for each analyte. The linear ranges were 1-100 µg/L for each examined
172 analyte with correlation coefficients of greater than 0.9888. The limits of detection (LODs) were evaluated
173 with signal-to-noise ratio (S/N) of 3 and the limits of quantification (LOQs) were evaluated with signal-to-
174 noise ratio (S/N) of 10. LODs and LOQs of solvent-based calibration curves were in the range of 0.01-1.33
175 µg/L and 0.04-4.42 µg/L, respectively.

176 3.3.3 Matrix effects

177 Aquatic products are rich in proteins and unsaturated fatty acids, as well as they contain a variety of
178 vitamins, minerals, trace elements and so on. Complex components cause ubiquitous matrix effects (signal
179 suppression and enhancement) during the LC-MS/MS analysis which may strongly affect the quantitative
180 accuracy and reproducibility in this study(GuoWangXiaoHuaiWangPanLiao & Liu 2016)¹⁴. Here, the matrix
181 effects of three subtracts were evaluated by comparing the calibration curves of the target antibiotics prepared
182 in solvent and in the matrix(HernandoFerrerUlaszewskaGarcía-ReyesMolina-Díaz & Fernández-Alba 2007)¹⁵,
183 which is calculated as:

$$184 \text{ Matrix effect (\%)} = (\text{Slope}_{\text{matrix-matched standard curve}} / \text{Slope}_{\text{solvent-based standard curve}} - 1) \times 100$$

185 Three sets of blank matrix samples were introduced to the mixed standard solution of different
186 concentrations (1, 5, 10, 25, 50, 100 µg/L). As listed in Table 3, among the three matrices of grass Carp,
187 *Penaeus vannamei* and *Scylla serrata*, matrix effects could still encountered in determining several antibiotics

188 such as lincomycin hydrochloride, clindamycin hydrochloride and tylosin. Therefore, matrix-matched standard
189 curves were applied to mitigate matrix effects for quantification of 49 antibiotics. The results of the regression
190 analysis showed that the correlation coefficients (R^2) of the matrix-matched standard curves of 49 antibiotics in
191 grass Carp, *Penaeus vannamei* and *Scylla serrata* ranged from 0.9900 to 0.9999, 0.9851 to 0.9998, 0.9908 to
192 0.9997, respectively which indicated excellent linearity.

193 Based on data obtained from matrix-matched standard curves of 49 antibiotics in grass Carp,
194 *Penaeus vannamei* and *Scylla serrata*, the range of the LODs were 0.05-2.40 $\mu\text{g}/\text{kg}$, 0.08-2.00 $\mu\text{g}/\text{kg}$
195 and 0.10-2.27 $\mu\text{g}/\text{kg}$, respectively. And LOQs were in the range of 0.16-8.00 $\mu\text{g}/\text{kg}$, 0.25-6.66 $\mu\text{g}/\text{kg}$
196 and 0.32-7.56 $\mu\text{g}/\text{kg}$, respectively. Hereby, the results of all the LODs and LOQs exhibited in Table 3 in
197 this research were satisfactory as compared with the MRLs.

198 3.3.4 Recovery and precision

199 In order to investigate the accuracy and precision of this method, recovery experiments were conducted at
200 different spiking levels of 10, 50, 100 $\mu\text{g}/\text{kg}$ (Table 4). Among the 49 antibiotics, except for lincomycin
201 hydrochloride whose recoveries were less than 60%, the recoveries of other antibiotics in three matrices were
202 generally greater than 70%. These results indicated that this method had a satisfactory stability and could meet
203 the actual detecting requirements of 49 antibiotics in aquatic products.

204 3.4 Application to real samples

205 In this study, 32 samples of aquatic products (including 12 grass Carp, 11 *Penaeus vannamei*, and 9 *Scylla*
206 *serrata*) bought from supermarkets were tested to display the applicability of this method. These samples were
207 dealt with the improved QuEChERS procedure and screened by UPLC-QTOF-MS. All antibiotic residues
208 were quantified using the matrix-matched calibration method, increasing the data accuracy. Results showed
209 that difluoxacin hydrochloride was detected in the samples of *Penaeus vannamei* whose amounts ranged from
210 1.5 to 7.0 $\mu\text{g}/\text{kg}$. MRLs of difluoxacin hydrochloride was 300 $\mu\text{g}/\text{kg}$ according to GB 31650-2019 announced
211 by MOA, China. Overall, all the concentrations of antibiotic residues in real samples were lower than their
212 MRLs, while other target antibiotics were below their LOQs.

213 4. Conclusions

214 Summing up, in this study, a fast, convenient, effective, economical and eco-friendly strategy based on

215 QuEChERS process was established to extract the antibiotics in aquatic products including grass Carp,
216 *Penaeus vannamei* and *Scylla serrata*. Using UPLC-QTOFMS platform and matrix-matched calibration
217 method to screen and quantify the 49 antibiotic residues, the study achieved satisfactory recoveries, significant
218 linearity and decent stability. Our method also possesses great potential in the analysis of various kinds of
219 antibiotic residues in aquatic products.

Figure 1

Fig. 1a Chromatogram of the three isomers of sulfamonomethoxine, sulfamethoxypyridazine and sulfameter with 0.1% formic acid water-acetonitrile as the mobile phase

using 0.1% formic acid water-acetonitrile as the mobile phases, it is difficult to separate sulfamonomethoxine and sulfamethoxypyridazine completely

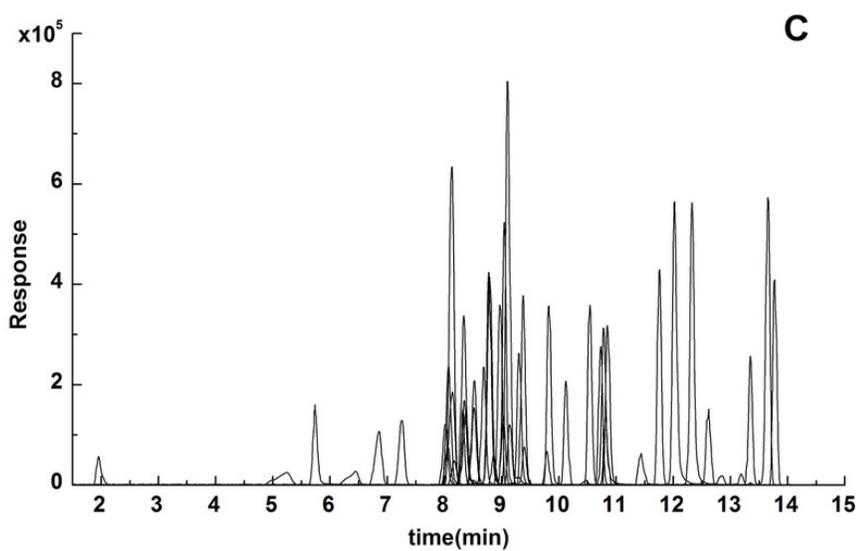

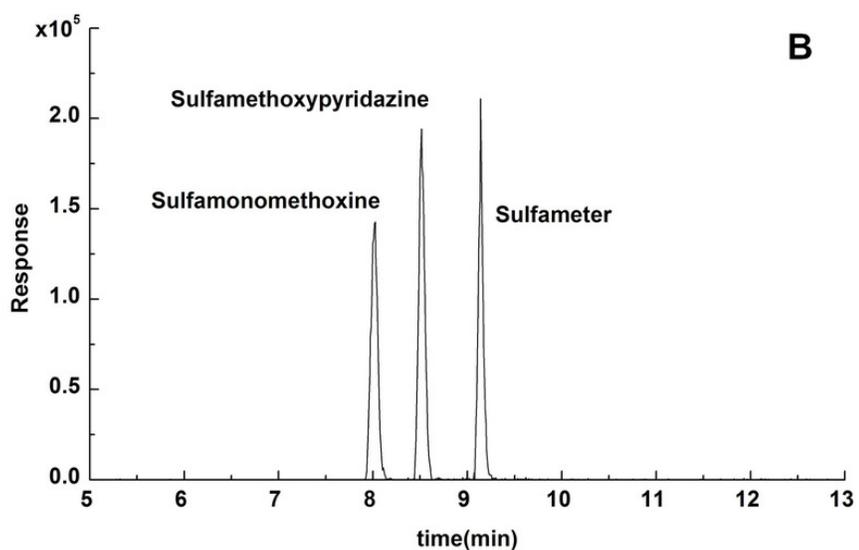

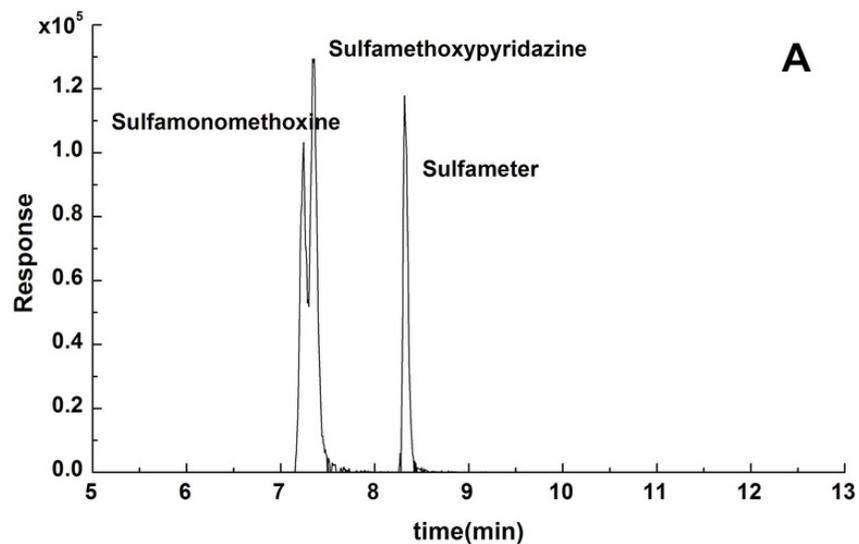

Figure 2

Fig.2 Effects of different extracting solvents on the recoveries of the 49 antibiotics

Using 3% acetic acid acetonitrile as the extractant, the average recoveries of 49 antibiotics in three matrices were 75.3%, 76.7%, 81.8%, respectively, which were higher than using 1% acetic acid-acetonitrile (v:v), 5% acetic acid-acetonitrile (v:v), and ethyl acetate for the extraction.

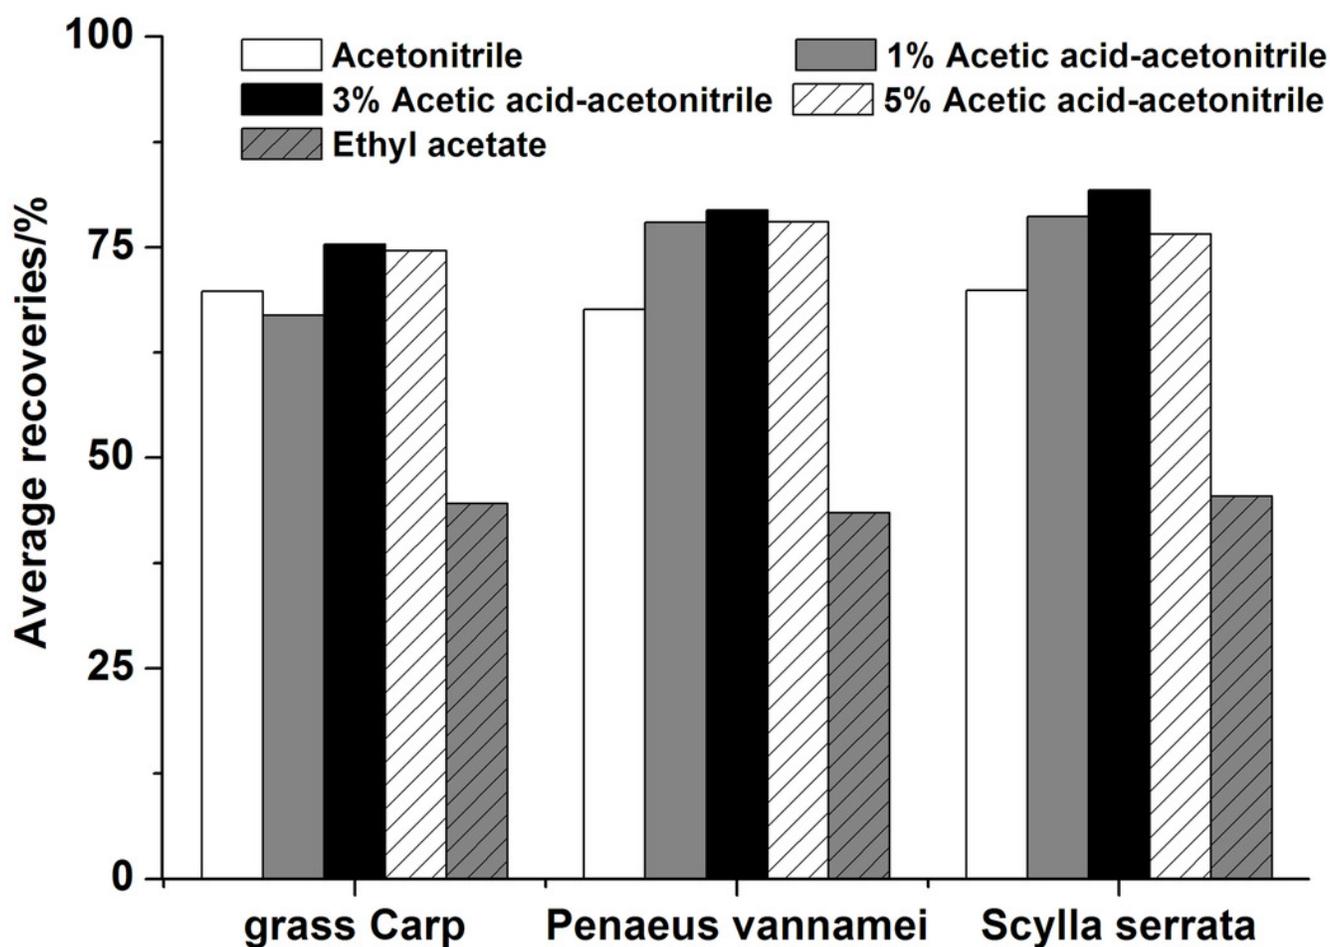

Figure 3

Fig. 3 Effects of 5 different sorbents on the average recoveries of the 49 antibiotics in grass Carp, *Penaeus vannamei* and *Scylla serrata*

The purification effects on grass Carp, *Penaeus vannamei* and *Scylla serrata* were shown when PSA, C18, ALU-N, PSA-C18 mixture, PSA-ALU-N mixture were investigated as purification sorbents.

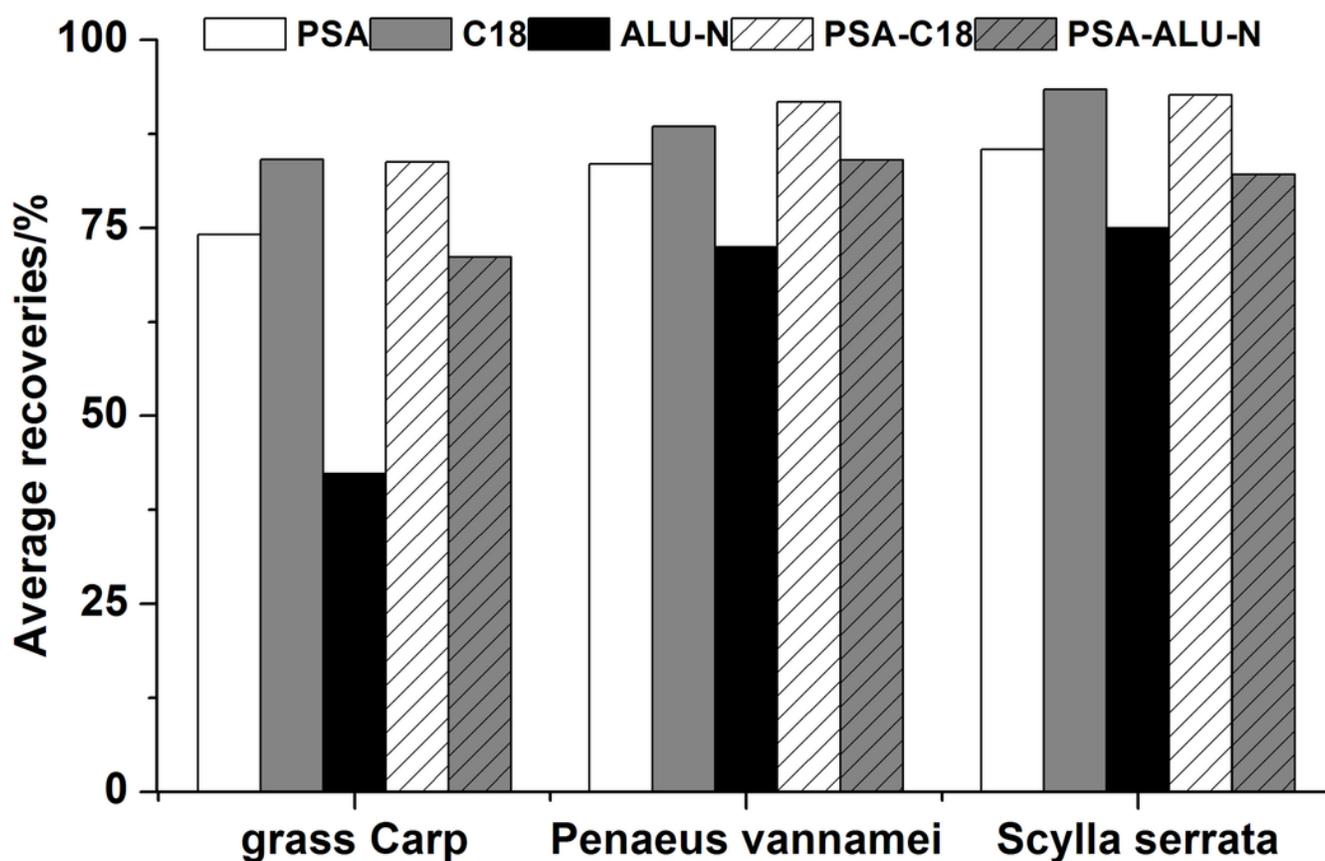

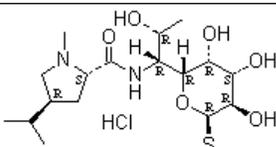

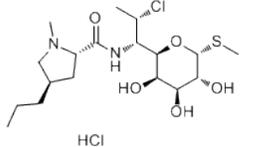

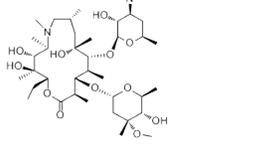

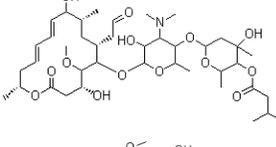

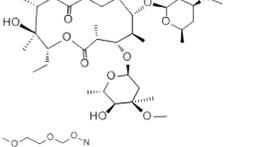

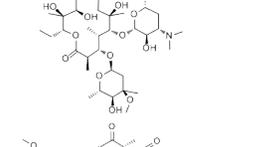

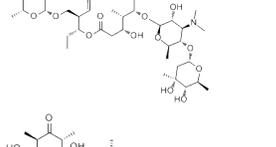

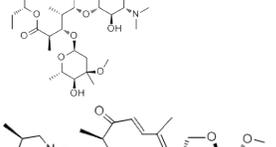

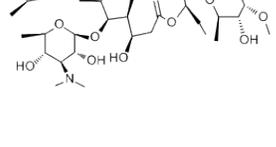

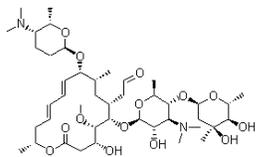

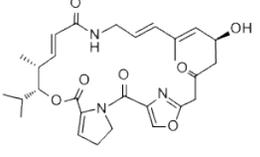

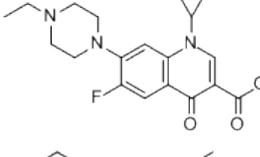

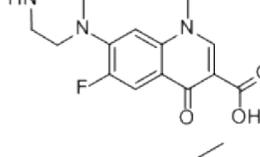

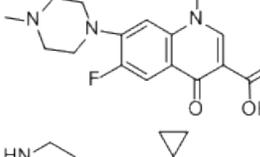

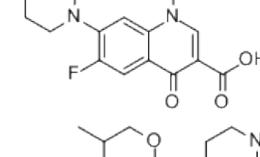

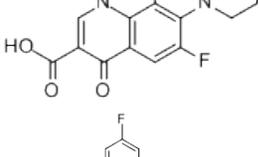

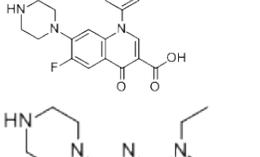

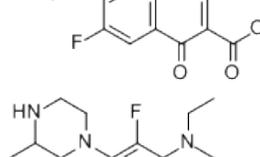

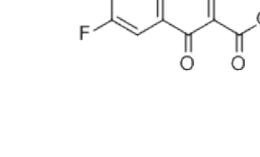

Table 1 (on next page)

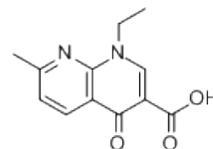

Table1 CAS number, molecular formula, molecular weight, RT, characteristic ions and structural formula of 49 antibiotics

1 **Table1 CAS number, molecular formula, molecular weight, RT, characteristic ions and structural**
 2 **formula of 49 antibiotics**

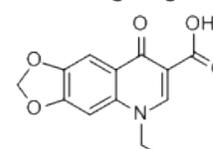

Antibiotic	CAS	Molecular formula	Molecular weight	RT (min)	Precursor ion (m/z)	Product ions (m/z)	Structural formula
Lincomycin hydrochloride	859-18-7	$C_{18}H_{35}ClN_2O_6S$	443.00	8.17	407.2213	126.1281,359.2176
