Scientific software registries and repositories improve software findability and research transparency, provide information for software citations, and foster preservation of computational methods in a wide range of disciplines. Registries and repositories play a critical role by supporting research reproducibility and replicability, but developing them takes effort and few guidelines are available to help prospective creators of these resources. To address this need, the FORCE11 Software Citation Implementation Working Group convened a Task Force to distill the experiences of the managers of existing resources in setting expectations for all stakeholders. In this paper, we describe the resultant best practices which include defining the scope, policies, and rules that govern individual registries and repositories, along with the background, examples, and collaborative work that went into their development. We believe that establishing specific policies such as those presented here will help other scientific software registries and repositories better serve their users and their disciplines.

16 ⁸FORCE11 Software Citation Implementation Working Group

17 ⁹Consortium of Scientific Software Registries and Repositories

18 **ABSTRACT**

19 Scientific software registries and repositories improve software findability and re-
20 search transparency, provide information for software citations, and foster preserva-
21 tion of computational methods in a wide range of disciplines. Registries and reposi-
22 tories play a critical role by supporting research reproducibility and replicability, but
23 developing them takes effort and few guidelines are available to help prospective
24 creators of these resources. To address this need, the *FORCE11 Software Citation*
25 *Implementation Working Group* convened a Task Force to distill the experiences of
26 the managers of existing resources in setting expectations for all stakeholders. In
27 this paper, we describe the resultant best practices which include defining the scope,
28 policies, and rules that govern individual registries and repositories, along with the
29 background, examples, and collaborative work that went into their development. We
30 believe that establishing specific policies such as those presented here will help
31 other scientific software registries and repositories better serve their users and their
32 disciplines.

33 **1 INTRODUCTION**

34 Research software is an essential constituent in scientific investigations (Wilson et al.,
35 2014; Momcheva and Tollerud, 2015; Hettrick, 2018; Lamprecht et al., 2020), as it is
36 often used to transform and prepare data, perform novel analyses on data, automate
37 manual processes, and visualize results reported in scientific publications (Howison
38 and Herbsleb, 2011). Research software is thus crucial for reproducibility and has
39 been recognized by the scientific community as a research product in its own right—

one that should be properly described, accessible, and credited by others (Smith et al., 2016; Chue Hong et al., 2021). As a result of the increasing importance of computational methods, communities such as Research Data Alliance (RDA) (Berman and Crosas, 2020)¹ and FORCE11 (Bourne et al., 2012)² emerged to enable collaboration and establish best practices. Numerous software services that enable open community development of and access to research source code, such as GitHub³ and Gitlab,⁴ appeared and found a role in science. General-purpose repositories, such as Zenodo (CERN and OpenAIRE, 2013) and FigShare (Thelwall and Kousha, 2016), have expanded their scope beyond data to include software, and new repositories, such as Software Heritage (Di Cosmo and Zacchioli, 2017), have been developed specifically for software. A large number of domain-specific research software registries and repositories have emerged for different scientific disciplines to ensure dissemination and reuse among their communities (Gentleman et al., 2004; Peckham et al., 2013; Greuel and Sperber, 2014; Allen and Schmidt, 2015; Gil et al., 2015, 2016).

Research software registries are typically indexes or catalogs of software metadata, without any code stored in them; while in *research software repositories*, software is both indexed and stored (Lamprecht et al., 2020). Both types of resource improve software discoverability and research transparency, provide information for software citations, and foster preservation of computational methods that might otherwise be lost over time, thereby supporting research reproducibility and replicability. Many provide or are integrated with other services, including indexing and archival services, that can be leveraged by librarians, digital archivists, journal editors and publishers, and researchers alike.

Transparency of the processes under which registries and repositories operate helps build trust with their user communities (Yakel et al., 2013; Frank et al., 2017). However, many domain research software resources have been developed independently, and thus policies amongst such resources are often heterogeneous and some may be omitted. Having specific policies in place ensures that users and administrators have reference documents to help define a shared understanding of the scope, practices, and rules that govern these resources.

Though recommendations and best practices for many aspects of science have been developed, no best practices existed that addressed the operations of software registries and repositories. To address this need, a Best Practices for Software Registries Task Force was proposed in June 2018 to the *FORCE11 Software Citation Implementation Working Group (SCIWG)*.⁵ In seeking to improve the services software resources provide, software repository maintainers came together to learn from each other and promote interoperability. Both common practices and missing practices unfolded in these exchanges. These practices led to the development of nine best practices that set expectations for both users and maintainers of the resource by defining

³<https://github.com/>

⁴<https://gitlab.com>

⁵<https://github.com/force11/force11-sciwg>

79 management of its contents and allowed usages as well as clarifying positions on
80 sensitive issues such as attribution.

81 In this paper, we expand on our pre-print “Nine Best Practices for Research Software
82 Registries and Repositories: A Concise Guide” ([Task Force on Best Practices for
83 Software Registries et al., 2020](#)) to describe our best practices and their development.
84 Our guidelines are actionable, have a general purpose, and reflect the discussion of
85 a community of more than 30 experts who handle over 14 resources (registries or
86 repositories) across different scientific domains. Each guideline provides a rationale,
87 suggestions, and examples based on existing repositories or registries. To reduce
88 repetition, we refer to registries and repositories collectively as “resources.”

89 The remainder of the paper is structured as follows. We first describe background and
90 related efforts in Section 2, followed by the methodology we used when structuring
91 the discussion for creating the guidelines (Section 3). We then describe the nine best
92 practices in Section 4, followed by a discussion (Section 5). Section 6 concludes the
93 paper by summarizing current efforts to continue the adoption of the proposed prac-
94 tices. Those who contributed to the development of this paper are listed in [Appendix
95 A](#), and links to example policies are given in [Appendix B](#). [Appendix C](#) provides up-
96 dated information about resources that have participated in crafting the best practices
97 and an overview of their main attributes.

98 2 BACKGROUND

99 In the last decade, much was written about a reproducibility crisis in science ([Baker,
100 2016](#)) stemming in large part from the lack of training in programming skills and the
101 unavailability of computational resources used in publications ([Merali, 2010; Peng,
102 2011; Morin et al., 2012](#)). On these grounds, national and international governments
103 have increased their interest in releasing artifacts of publicly-funded research to the
104 public ([Office of Science and Technology Policy, 2016; Directorate-General for Re-
105 search and Innovation \(European Commission\), 2018; Australian Research Council,
106 2018; Chen et al., 2019; Ministère de l’Enseignement supérieur, de la Recherche et
107 de l’Innovation, 2021](#)), and scientists have appealed to colleagues in their field to re-
108 lease software to improve research transparency ([Weiner et al., 2009; Barnes, 2010;
109 Ince et al., 2012](#)) and efficiency ([Grosbol and Tody, 2010](#)). Open Science initiatives
110 such as RDA and FORCE11 have emerged as a response to these calls for greater
111 transparency and reproducibility. Journals introduced policies encouraging (or even
112 requiring) that data and software be openly available to others ([Editorial staff, 2019;
113 Fox et al., 2021](#)). New tools have been developed to facilitate depositing research data
114 and software in a repository ([Baruch, 2007; CERN and OpenAIRE, 2013; Di Cosmo
115 and Zacchiroli, 2017; Clyburne-Sherin et al., 2019; Brinckman et al., 2019; Trisovic
116 et al., 2020](#)) and consequently, make them citable so authors and other contributors
117 gain recognition and credit for their work ([Soito and Hwang, 2017; Du et al., 2021](#)).

118 Support for disseminating research outputs has been proposed with FAIR and FAIR4RS
119 principles that state shared digital artifacts, such as data and software, should be Find-
120 able, Accessible, Interoperable, and Reusable ([Wilkinson et al., 2016; Lamprecht
121 et al., 2020; Katz et al., 2021; Chue Hong et al., 2021](#)). Conforming with the FAIR

principles for published software (Lamprecht et al., 2020) requires facilitating its discoverability, preferably in domain-specific resources (Jiménez et al., 2017). These resources should contain machine-readable metadata to improve the discoverability (Findable) and accessibility (Accessible) of research software through search engines or from within the resource itself. Furthering interoperability in FAIR is aided through the adoption of community standards *e.g.*, schema.org (Guha et al., 2016) or the ability to translate from one resource to another. The CodeMeta initiative (Jones et al., 2017) achieves this translation by creating a “Rosetta Stone” which maps the metadata terms used by each resource to a common schema. The CodeMeta schema⁶ is an extension of schema.org which adds ten new fields to represent software-specific metadata. To date, CodeMeta has been adopted for representing software metadata by many repositories.^{7,8}

As the usage of computational methods continues to grow, recommendations for improving research software have been proposed (Stodden et al., 2016) in many areas of science and software, as can be seen by the series of “Ten Simple Rules” articles offered by PLOS (Dashnow et al., 2014), sites such as AstroBetter,⁹ courses to improve skills such as those offered by The Carpentries,¹⁰ and attempts to measure the adoption of recognized best practices (Serban et al., 2020; Trisovic et al., 2022). Our quest for best practices complements these efforts by providing guides to the specific needs of research software registries and repositories.

3 METHODOLOGY

The best practices presented in this paper were developed by an international Task Force of the FORCE11 Software Citation Implementation Working Group (SCIWG). The Task Force was proposed in June 2018 by author Alice Allen, with the goal of developing a list of best practices for software registries and repositories. Working Group members and a broader group of managers of domain specific software resources formed the inaugural group. The resulting Task Force members were primarily managers and editors of resources from Europe, United States, and Australia. Due to the range in time zones, the Task Force held two meetings seven hours apart, with the expectation that, except for the meeting chair, participants would attend one of the two meetings. We generally refer to two meetings on the same day with the singular “meeting” in the discussions to follow.

The inaugural Task Force meeting (Feb, 2019) was attended by eighteen people representing fourteen different resources. Participants introduced themselves and provided some basic information about their resources, including repository name, starting year, number of records, and scope (discipline-specific or general purpose), as well as services provided by each resource (*e.g.*, support of software citation, software deposits,

Question	#Yes	#No	#Other
Is the resource discipline-specific?	6	8	0
Does the resource accept software only?	8	6	0
Does the resource require a software deposit?	2	12	0
Does the resource accept software deposits?	10	4	0
Can the resource mint DOIs?	6	8	0
Is the resource actively curated?	10	1	3
Can the resource be used to cite software?	11	2	1

Table 1. Overview of the information shared by the 14 resources which participated in the first Task Force meeting.

and DOI minting). Table 1 presents an overview of the collected responses, which highlight the efforts of the Task Force chairs to bring together both discipline-specific and general purpose resources. The “Other” category indicates that the answer needed clarifying text (e.g., for the question “is the repository actively curated?” some repositories are not manually curated, but have validation checks). Appendix C provides additional information on the questions asked to resource managers (Table C.1) and their responses (tables C.2, C.3 and C.4).

During the inaugural Task Force meeting, the chair laid out the goal of the Task Force, and the group was invited to brainstorm to identify commonalities for building a list of best practices. Participants also shared challenges they had faced in running their resources and policies they had enacted to manage these resources. The result of the brainstorming and discussion was a list of ideas collected in a common document.

Starting in May 2019 and continuing through the rest of 2019, the Task Force met on the third Thursday of each month and followed an iterative process to discuss, add to, and group ideas; refine and clarify the ideas into different practices, and define the practices more precisely. It was clear from the onset that, though our resources have goals in common, they are also very diverse and would be best served by best practices that were descriptive rather than prescriptive. We reached consensus on whether a practice should be a *best* practice through discussion and informal voting. Each best practice was given a title and a list of questions or needs that it addressed.

Our initial plan aimed at holding two Task Force meetings on the same day each month, in order to follow a common agenda with independent discussions built upon the previous month’s meeting. However, the later meeting was often advantaged by the earlier discussion. For instance, if the early meeting developed a list of examples for one of the guidelines, the late meeting then refined and added to the list. Hence, discussions were only duplicated when needed, e.g., where there was no consensus in the early group, and often proceeded in different directions according to the group’s expertise and interest. Though we had not anticipated this, we found that holding two meetings each month on the same day accelerated the work, as work done in the second meeting of the day generally continued rather than repeating work done in the first meeting.

190 The resulting consensus from the meetings produced a list of the most broadly ap-
 191 plicable practices, which became the initial list of best practices participants drew
 192 from during a two-day workshop, funded by the Sloan Foundation and held at the
 193 University of Maryland College Park, in November, 2019 (*Scientific Software Registry*
 194 *Collaboration Workshop*). A goal of the workshop was to develop the final recom-
 195 mendations on best practices for repositories and registries to the FORCE11 SCIWG.
 196 The workshop included participants outside the Task Force resulting in a broader
 197 set of contributions to the final list. In 2020, this group made additional refinements
 198 to the best practices during virtual meetings and through online collaborative writ-
 199 ing producing in the guidelines described in the next section. The Task Force then
 200 transitioned into the SciCodes consortium.¹¹ SciCodes is a permanent community
 201 for research software registries and repositories with a particular focus on these best
 202 practices. SciCodes continued to collect information about involved registries and
 203 repositories, which are listed in [Appendix C](#). We also include some analysis of the
 204 number of entries and date of creation of member resources. [Appendix A](#) lists the
 205 people who participated in these efforts.

206 **4 BEST PRACTICES FOR REPOSITORIES AND REGISTRIES**

207 Our recommendations are provided as nine separate policies or statements, each pre-
 208 sented below with an explanation as to why we recommend the practice, what the
 209 practice describes, and specific considerations to take into account. The last paragraph
 210 of each best practice includes one or two examples and a link to [Appendix B](#), which
 211 contains many examples from different registries and repositories.

212 These nine best practices, though not an exhaustive list, are applicable to the varied
 213 resources represented in the Task Force, so are likely to be broadly applicable to other
 214 scientific software repositories and registries. We believe that adopting these practices
 215 will help document, guide, and preserve these resources, and put them in a stronger
 216 position to serve their disciplines, users, and communities.¹²

217 **4.1 Provide a public scope statement**

218 The landscape of research software is diverse and complex due to the overlap between
 219 scientific domains, the variety of technical properties and environments, and the addi-
 220 tional considerations resulting from funding, authors' affiliation, or intellectual prop-
 221 erty. A scope statement clarifies the type of software contained in the repository or
 222 indexed in the registry. Precisely defining a scope, therefore, helps those users of the
 223 resource who are looking for software to better understand the results they obtained.

224 Moreover, given that many of these resources accept submission of software packages,
 225 providing a precise and accessible definition will help researchers determine whether
 226 they should register or deposit software, and curators by making clear what is out
 227 of scope for the resource. Overall, a public scope manages the expectations of the
 228 potential depositor as well as the software seeker. It informs both what the resource
 229 does and does not contain.

11<http://scicodes.net>

12Please note that the information provided in this paper does not constitute legal advice.

230 The scope statement should describe:

- 231 • What is accepted, and acceptable, based on criteria covering scientific disci-
232 pline, technical characteristics, and administrative properties
- 233 • What is not accepted, *i.e.* characteristics that preclude their incorporation in the
234 resource
- 235 • Notable exceptions to these rules, if any

236 Particular criteria of relevance include the scientific community being served and
237 the types of software listed in the registry or stored in the repository, such as source
238 code, compiled executables, or software containers. The scope statement may also
239 include criteria that must be satisfied by accepted software, such as whether certain
240 software quality metrics must be fulfilled or whether a software project must be used
241 in published research. Availability criteria can be considered, such as whether the
242 code has to be publicly available, be in the public domain and/or have a license from a
243 predefined set, or whether software registered in another registry or repository will be
244 accepted.

245 An illustrating example of such a scope statement is the editorial policy¹³ published
246 by the Astrophysics Source Code Library (ASCL) (Allen et al., 2013), which states
247 that it includes only software source code used in published astronomy and astro-
248 physics research articles, and specifically excludes software available only as a binary
249 or web service. Though the ASCL's focus is on research documented in peer-reviewed
250 journals, its policy also explicitly states that it accepts source code used in successful
251 theses. Other examples of [scope statements](#) can be found in [Appendix B](#).

252 4.2 Provide guidance for users

253 Users accessing a resource to search for entries and browse or retrieve the descrip-
254 tion(s) of one or more software entries have to understand how to perform such ac-
255 tions. Although this guideline potentially applies to many public online resources,
256 especially research databases, the potential complexity of the stored metadata and
257 the curation mechanisms can seriously impede the understandability and usage of
258 software registries and repositories.

259 User guidance material may include:

- 260 • How to perform common user tasks, such as searching the resource, or access-
261 ing the details of an entry
- 262 • Answers to questions that are often asked or can be anticipated, *e.g.*, with Fre-
263 quently Asked Questions or tips and tricks pages
- 264 • Who to contact for questions or help

265 A separate section in these guidelines on the [Conditions of use policy](#) covers terms of
266 use of the resource and how best to cite records in a resource and the resource itself.

¹³<https://ascl.net/wordpress/submissions/editorial-policy/>

267 Guidance for users who wish to contribute software is covered in the next section,
268 *Provide guidance to software contributors*.

269 When writing guidelines for users, it is advisable to identify the types of users your
270 resource has or could potentially have and corresponding use cases. Guidance itself
271 should be offered in multiple forms, such as in-field prompts, linked explanations, and
272 completed examples. Any machine-readable access, such as an API, should be fully
273 described directly in the interface or by providing a pointer to existing documentation,
274 and should specify which formats are supported (*e.g.*, JSON-LD, XML) through
275 content negotiation if it is enabled.

276 Examples of such elements include, for instance, the bio.tools registry (Ison et al.,
277 2019) API user guide,¹⁴ or the ORNL DAAC (ORNL, 2013) instructions for data
278 providers.¹⁵ Additional examples of *user guidance* can be found in Appendix B.

279 4.3 Provide guidance to software contributors

280 Most software registries and repositories rely on a community model, whereby ex-
281 ternal contributors will provide software entries to the resource. The scope statement
282 will already have explained *what* is accepted and what is not; the contributor policy
283 addresses *who* can add or change software entries and the processes involved.

284 The contributor policy should therefore describe:

- 285 • Who can or cannot submit entries and/or metadata
- 286 • Required and optional metadata expected for deposited software
- 287 • Review process, if any
- 288 • Curation process, if any
- 289 • Procedures for updates (*e.g.*, who can do it, when it is done, how is it done)

290 Topics to consider when writing a contributor policy include whether the author(s) of
291 a software entry will be contacted if the contributor is not also an author and whether
292 contact is a condition or side-effect of the submission. Additionally, a contributor
293 policy should specify how persistent identifiers are assigned (if used) and should
294 state that depositors must comply with all applicable laws and not be intentionally
295 malicious.

296 Such material is provided in resources such as the Computational Infrastructure for
297 Geodynamics (Hwang and Kellogg, 2017) software contribution checklist¹⁶ and the
298 CoMSES Net Computational Model Library (Janssen et al., 2008) model archival
299 tutorial.¹⁷ Additional examples of *guidance for software contributors* can be found in
300 Appendix B.

¹⁴https://biotools.readthedocs.io/en/latest/api_usage_guide.html

¹⁵<https://daac.ornl.gov/submit/>

¹⁶<https://geodynamics.org/cig/dev/code-donation/checklist/>

¹⁷<https://forum.comses.net/t/archiving-your-model-1-getting-started/7377>

301 4.4 Establish an authorship policy

302 Because research software is often a research product, it is important to report au-
303 thorship accurately, as it allows for proper scholarly credit and other types of attribu-
304 tions (Smith et al., 2016). However, even though authorship should be defined at the
305 level of a given project, it can prove complicated to determine (Alliez et al., 2019).
306 Roles in software development can widely vary as contributors change with time and
307 versions, and contributions are difficult to gauge beyond the “commit,” giving rise to
308 complex situations. In this context, establishing a dedicated policy ensures that people
309 are given due credit for their work. The policy also serves as a document that admin-
310 istrators can turn to in case disputes arise and allows proactive problem mitigation,
311 rather than having to resort to reactive interpretation. Furthermore, having an author-
312 ship policy mirrors similar policies by journals and publishers and thus is part of a
313 larger trend. Note that the authorship policy will be communicated at least partially
314 to users through guidance provided to software contributors. Resource maintainers
315 should ensure this policy remains consistent with the citation policies for the registry
316 or repository (usually, the citation requirements for each piece of research software
317 are under the authority of its owners).

318 The authorship policy should specify:

- 319 • How authorship is determined *e.g.*, a stated criteria by the contributors and/or
- 320 the resource
- 321 • Policies around making changes to authorship
- 322 • The conflict resolution processes adopted to handle authorship disputes

323 When defining an authorship policy, resource maintainers should take into consider-
324 ation whether those who are not coders, such as software testers or documentation
325 maintainers, will be identified or credited as authors, as well as criteria for ordering
326 the list of authors in cases of multiple authors, and how the resource handles large
327 numbers of authors and group or consortium authorship. Resources may also include
328 guidelines about how changes to authorship will be handled so each author receives
329 proper credit for their contribution. Guidelines can help facilitate determining every
330 contributors’ role. In particular, the use of a credit vocabulary, such as the Contributor
331 Roles Taxonomy (Allen et al., 2019), to describe authors’ contributions should be
332 considered for this purpose.¹⁸

333 An example of authorship policy is provided in the Ethics Guidelines¹⁹ and the sub-
334 mission guide authorship section²⁰ of the *Journal of Open Source Software* (Katz
335 et al., 2018), which provides rules for inclusion in the authors list. Additional exam-
336 ples of [authorship policies](#) can be found in [Appendix B](#).

337 4.5 Document and share your metadata schema

338 The structure and semantics of the information stored in registries and repositories is
339 sometimes complex, which can hinder the clarity, discovery, and reuse of the entries

¹⁸<http://credit.niso.org/>

¹⁹<https://joss.theoj.org/about#ethics>

²⁰<https://joss.readthedocs.io/en/latest/submitting.html#authorship>

included in these resources. Publicly posting the metadata schema used for the entries helps individual and organizational users interested in a resource's information understand the structure and properties of the deposited information. The metadata structure helps to inform users how to interact with or ingest records in the resource. A metadata schema mapped to other schemas and an API specification can improve the interoperability between registries and repositories.

This practice should specify:

- The schema used and its version number. If a standard or community schema, such as *CodeMeta* (Jones et al., 2017) or *schema.org* (Guha et al., 2016) is used, the resource should reference its documentation or official website. If a custom schema is used, formal documentation such as a description of the schema and/or a data dictionary should be provided.
- Expected metadata when submitting software, including which fields are required and which are optional, and the format of the content in each field.

To improve the readability of the metadata schema and facilitate its translation to other standards, resources may provide a mapping (from the metadata schema used in the resource) to published standard schemas, through the form of a “cross-walk” (e.g., the CodeMeta cross-walk²¹) and include an example entry from the repository that illustrates all the fields of the metadata schema. For instance, extensive documentation²² is available for the biotoolsSchema (Ison et al., 2021) format, which is used in the bio.tools registry. Another example is the OntoSoft vocabulary,²³ used by the OntoSoft registry (Gil et al., 2015, 2016) and available in both machine-readable and human readable formats. Additional examples of [metadata schemas](#) can be found in [Appendix B](#).

4.6 Stipulate conditions of use

The *conditions of use* document the terms under which users may use the contents provided by a website. In the case of software registries and repositories, these conditions should specifically state how the metadata regarding the entities of a resource can be used, attributed, and/or cited, and provide information about the licenses used for the code and binaries. This policy can forestall potential liabilities and difficulties that may arise, such as claims of damage for misinterpretation or misapplication of metadata. In addition, the conditions of use should clearly state how the metadata can and cannot be used, including for commercial purposes and in aggregate form.

This document should include:

- Legal disclaimers about the responsibility and liability borne by the registry or repository
- License and copyright information, both for individual entries and for the registry or repository as a whole

²³<http://ontosoft.org/software>

- 378 • Conditions for the use of the metadata, including prohibitions, if any
- 379 • Preferred format for citing software entries
- 380 • Preferred format for attributing or citing the resource itself

381 When writing conditions of use, resource maintainers might consider what license
 382 governs the metadata, if licensing requirements apply for findings and/or derivatives
 383 of the resource, and whether there are differences in the terms and license for commer-
 384 cial versus noncommercial use. Restrictions on the use of the metadata may also be
 385 included, as well as a statement to the effect that the registry or repository makes no
 386 guarantees about completeness and is not liable for any damages that could arise from
 387 the use of the information. Technical restrictions, such as conditions of use of the API
 388 (if one is available), may also be mentioned.

389 Conditions of use can be found for instance for DOE CODE (Ensor et al., 2017),
 390 which in addition to the general conditions of use²⁴ specifies that the rules for usage
 391 of the hosted code²⁵ are defined by their respective licenses. Additional examples of
 392 conditions of use policies can be found in Appendix B.

393 4.7 State a privacy policy

394 Privacy policies define how personal data about users are stored, processed, exchanged
 395 or removed. Having a privacy policy demonstrates a strong commitment to the privacy
 396 of users of the registry or repository and allows the resource to comply with the legal
 397 requirement of many countries in addition to those a home institution and/or funding
 398 agencies may impose.

399 The privacy policy of a resource should describe:

- 400 • What information is collected and how long it is retained
- 401 • How the information, especially any personal data, is used
- 402 • Whether tracking is done, what is tracked, and how (e.g., Google Analytics)
- 403 • Whether cookies are used

404 When writing a privacy policy, the specific personal data which are collected should
 405 be detailed, as well as the justification for their resource, and whether these data are
 406 sold and shared. Additionally, one should list explicitly the third-party tools used
 407 to collect analytic information and potentially reference their privacy policies. If
 408 users can receive emails as a result of visiting or downloading content, such potential
 409 solicitations or notifications should be announced. Measures taken to protect users'
 410 privacy and whether the resource complies with the *European Union Directive on*
 411 *General Data Protection Regulation*²⁶ (GDPR) or other local laws, if applicable,
 412 should be explained.²⁷ As a precaution, the statement can reserve the right to make

²⁴<https://www.osti.gov/disclaim>

²⁵<https://www.osti.gov/doecode/faq#are-there-restrictions>

²⁶<https://gdpr-info.eu/>

²⁷In the case of GDPR, the regulation applies to all European user personal data, even if the re-
 source is not located in Europe.

changes to this privacy policy. Finally, a mechanism by which users can request the removal of such information should be described.

For example, the SciCrunch's (Grethe et al., 2014) privacy policy²⁸ details what kind of personal information is collected, how it is collected, and how it may be reused, including by third-party websites through the use of cookies. Additional examples of privacy policies can be found in Appendix B.

4.8 Provide a retention policy

Many software registries and repositories aim to facilitate the discovery and accessibility of the objects they describe, *e.g.*, enabling search and citation, by making the corresponding records permanently accessible. However, for various reasons, even in such cases maintainers and curators may have to remove records. Common examples include removing entries that are outdated, no longer meet the scope of the registry, or are found to be in violation of policies. The resource should therefore document retention goals and procedures so that users and depositors are aware of them.

The retention policy should describe:

- The length of time metadata and/or files are expected to be retained
- Under what conditions metadata and/or files are removed
- Who has the responsibility and ability to remove information
- Procedures to request that metadata and/or files be removed

The policy should take into account whether best practices for persistent identifiers are followed, including resolvability, retention, and non-reuse of those identifiers. The retention time provided by the resource should not be too prescriptive (*e.g.*, “for the next 10 years”), but rather it should fit within the context of the underlying organization(s) and its funding. This policy should also state who is allowed to edit metadata, delete records, or delete files, and how these changes are performed to preserve the broader consistency of the registry. Finally, the process by which data may be taken offline and archived as well as the process for its possible retrieval should be thoroughly documented.

As an example, Bioconductor (Gentleman et al., 2004) has a deprecation process through which software packages are removed if they cannot be successfully built or tested, or upon specific request from the package maintainer. Their policy²⁹ specifies who initiates this process and under which circumstances, as well as the successive steps that lead to the removal of the package. Additional examples of retention policies can be found in Appendix B.

4.9 Disclose your end-of-life policy

Despite their usefulness, the long-term maintenance, sustainability, and persistence of online scientific resources remains a challenge, and published web services or databases can disappear after a few years (Veretnik et al., 2008; Kern et al., 2020).

²⁸<https://scicrunch.org/page/privacy>

²⁹<https://bioconductor.org/developers/package-end-of-life/>

Sharing a clear end-of-life policy increases trust in the community served by a registry or repository. It demonstrates a thoughtful commitment to users by informing them that provisions for the resource have been considered should the resource close or otherwise end its services for its described artifacts. Such a policy sets expectations and provides reassurance as to how long the records within the registry will be findable and accessible in the future.

This policy should describe:

- Under what circumstances the resource might end its services
- What consequences would result from closure
- What will happen to the metadata and/or the software artifacts contained in the resource in the event of closure
- If long-term preservation is expected, where metadata and/or software artifacts will be migrated for preservation
- How a migration will be funded

Publishing an end-of-life policy is an opportunity to consider, in the event a resource is closed, whether the records will remain available, and if so, how and for whom, and under which conditions, such as archived status or “read-only.” The restrictions applicable to this policy, if any, should be considered and detailed. Establishing a formal agreement or memorandum of understanding with another registry, repository, or institution to receive and preserve the data or project, if applicable, might help to prepare for such a liability.

Examples of such policies include the Zenodo end-of-life policy,³⁰ which states that if Zenodo ceases its services, the data hosted in the resource will be migrated and the DOIs provided would be updated to resolve to the new location (currently unspecified). Additional examples of [end-of-life policies](#) can be found in [Appendix B](#).

A summary of the practices presented in this section can be found in [Table 2](#).

5 DISCUSSION

The best practices described above serve as a guide for repositories and registries to provide better service to their users, ranging from software developers and researchers to publishers and search engines, and enable greater transparency about the operation of their described resources. Implementing our practices provides users with significant information about *how* different resources operate, while preserving important institutional knowledge, standardizing expectations, and guiding user interactions.

For instance, a public scope statement and guidance for users may directly impact usability and, thus, the popularity of the repository. Resources including tools with a simple design and unambiguous commands, as well as infographic guides or video tutorials, ease the learning curve for new users. The guidance for software contributions, conditions of use, and sharing the metadata schema used may help eager users

³⁰<https://help.zenodo.org/>

489 contribute new functionality or tools, which may also help in creating a community
490 around a resource. A privacy policy has become a requirement across geographic
491 boundaries and legal jurisdictions. An authorship policy is critical in facilitating col-
492 laborative work among researchers and minimizing the chances for disputes. Finally,
493 retention and end-of-life policies increase the trust and integrity of a repository ser-
494 vice.

Table 2. Summary of the best practices with recommendations and examples.

Practice, description and examples	Recommendations
1. Provide a public scope statement Informs both software depositor and resource seeker what the collection does and does not contain. Example: ASCL editorial policy .	<ul style="list-style-type: none"> • What is accepted, and acceptable, based on criteria covering scientific discipline, technical characteristics, and administrative properties • What is not accepted, i.e. characteristics that preclude their incorporation in the resource • Notable exceptions to these rules, if any
2. Provide guidance for users Helps users accessing a resource understand how to perform tasks like searching, browsing, and retrieving software entries. Example: bio.tools registry API user guide .	<ul style="list-style-type: none"> • How to perform common user tasks, like searching for collection, or accessing the details of an entry • Answers to questions that are often asked or can be anticipated • Point of contact for help and questions
3. Provide guidance to software contributors Specifies who can add or change software entries and explains the necessary processes. Example: Computational Infrastructure for Geodynamics contribution checklist .	<ul style="list-style-type: none"> • Who can or cannot submit entries and/or metadata • Required and optional metadata expected from software contributors • Procedures for updates, review process, curation process
4. Establish an authorship policy Ensures that contributors are given due credit for their work and to resolve disputes in case of conflict. Example: JOSS authorship policy .	<ul style="list-style-type: none"> • How authorship is determined e.g., a stated criteria by the contributors and/or the resource • Policies around making changes to authorship • Define the conflict resolution processes
5. Document and share your metadata schema Revealing the metadata schema used helps users understand the structure and properties of the deposited information. Example: OntoSoft vocabulary from the OntoSoft registry .	<ul style="list-style-type: none"> • Specify the used schema and its version number. Add reference to its documentation or official website. If a custom schema is used, provide documentation. • Expected metadata when submitting software

6. Stipulate conditions of use

Documents the terms under which users may use the provided resources, including metadata and software.

Example: [DOE CODE acceptable use policy](#).

- Legal disclaimers about the responsibility and liability borne by the resource
- License and copyright information, both for individual entries and for the resource as a whole
- Conditions for the use of the metadata, including prohibitions, if any
- Preferred format for citing software entries; preferred format for attributing or citing the resource itself

7. State a privacy policy

Defines how personal data about users are stored, processed, exchanged, or removed.

Example: [SciCrunch's privacy policy](#).

- What information is collected and how long it is retained
- How the information, especially any personal data, is used
- Whether tracking is done, what is tracked, and how; whether cookies are used

8. Provide a retention policy

Helps both users and depositors understand and anticipate retention goals and procedures.

Example: [Bioconductor package deprecation](#).

- The length of time metadata and/or files are expected to be retained
- Under what conditions metadata and/or files are removed
- Who has the responsibility and ability to remove information; procedures to request that metadata and/or files be removed

9. Disclose end-of-life policy

Informs both users and depositors of how long the records within the resource will be findable and accessible in the future.

Example: [Zenodo end-of-life policy](#).

- Circumstances under which the resource might end its services
- What consequences would result from closure
- What will happen to the metadata and/or the software artifacts contained in the resource in the event of closure
- If long-term preservation is expected, where metadata and/or software artifacts will be migrated for preservation; how a migration will be funded

Policies affecting a single community or domain were deliberately omitted when developing the best practices. First, an exhaustive list would have been a barrier to adoption and not applicable to every repository since each has a different perspective, audience, and motivation that drives policy development for their organization. Second, best practices that regulate the content of a resource are typically domain-specific to the artifact and left to resources to stipulate based on their needs. Participants in the 2019 Scientific Software Registry Collaboration Workshop were surprised to find that only four metadata elements were shared by all represented resources.³¹ The diversity of our resources precludes prescriptive requirements, such as requiring specific metadata for records, so these were also deliberately omitted in the proposed best practices.

Hence, we focused on broadly applicable practices considered important by various

³¹The elements were: software name, description, keywords, and URL.

resources. For example, amongst the participating registries and repositories, very few had codes of conduct that govern the behavior of community members. Codes of conduct are warranted if resources are run as part of a community, especially if comments and reviews are solicited for deposits. In contrast, a code of conduct would be less useful for resources whose primary purpose is to make software and software metadata available for reuse. However, this does not negate their importance and their inclusion as best practices in other arenas concerning software.

As noted by the FAIR4RS movement, software is different than data, motivating the need for a separate effort to address software resources (Lamprecht et al., 2020; Katz et al., 2016). Even so, there are some similarities, and our effort complements and aligns well with recent guidelines developed in parallel to increase the transparency, responsibility, user focus, sustainability, and technology of data repositories. For example, both the TRUST Principles (Lin et al., 2020) and CoreTrustSeal Requirements Standards and Board (2019) call for a repository to provide information on its scope and list the terms of use of its metadata to be considered compliant with TRUST or CoreTrustSeal, which aligns with our practices “*Provide a public scope statement*” and “*Stipulate conditions of use*”. CoreTrustSeal and TRUST also require that a repository consider continuity of access, which we have expressed as the practice to “*Disclosing your end-of-life policy*”. Our best practices differ in that they do not address, for example, staffing needs nor professional development for staff, as CoreTrustSeal requires, nor do our practices address protections against cyber or physical security threats, as the TRUST principles suggest. Inward-facing policies, such as documenting internal workflows and practices, are generally good in reducing operational risks, but internal management practices were considered out of scope of our guidelines.

Figure 1 shows the number of resources that support (partially or in their totality) each best practice. Though we see the proposed best practices as critical, many of the repositories that have actively participated in the discussions (14 resources in total) have yet to implement every one of them. We have observed that the first three practices (providing public scope statement, add guidance for users and for software contributors) have the widest adoption, while the retention, end-of-life, and authorship policy the least. Understanding the lag in the implementation across all of the best practices requires further engagement with the community.

Improving the adoption of our guidelines is one of the goals of SciCodes,³² a recent consortium of scientific software registries and repositories. SciCodes evolved from the Task Force as a permanent community to continue the dialogue and share information between domains, including sharing of tools and ideas. SciCodes has also prioritized improving software citation (complementary to the efforts of the FORCE11 SCIWG) and tracking the impact of metadata and interoperability. In addition, SciCodes aims to understand barriers to implementing policies, ensure consistency between various best practices, and continue advocacy for software support by continuing dialogue between registries, repositories, researchers, and other stakeholders.

³²<http://scicodes.net>

Figure 1. Number of resources supporting each best practice, out of 14 resources.

6 CONCLUSIONS

The dissemination and preservation of research material, where repositories and registries play a key role, lies at the heart of scientific advancement. This paper introduces nine best practices for research software registries and repositories. The practices are an outcome of a Task Force of the FORCE11 Software Citation Implementation Working Group and reflect the discussion, collaborative experiences, and consensus of over 30 experts and 14 resources.

The best practices are non-prescriptive, broadly applicable, and include examples and guidelines for their adoption by a community. They specify establishing the working domain (scope) and guidance for both users and software contributors, address legal concerns with privacy, use, and authorship policies, enhance usability by encouraging metadata sharing, and set expectations with retention and end-of-life policies. However, we believe additional work is needed to raise awareness and adoption across resources from different scientific disciplines. Through the SciCodes consortium, our goal is to continue implementing these practices more uniformly in our own registries and repositories and reduce the burdens of adoption. In addition to completing the adoption of these best practices, SciCodes will address topics such as tracking the impact of good metadata, improving interoperability between registries, and making our metadata discoverable by search engines and services such as Google Scholar, ORCID, and discipline indexers.

ACKNOWLEDGEMENTS

The best practices presented here were proposed and developed by a Task Force of the FORCE11 Software Citation Implementation Working Group. The following authors, randomly ordered, contributed equally to discussion, conceptualization, writing, reviewing, and editing this paper: Daniel Garijo, Lorraine Hwang, Hervé Ménager,

573 Alice Allen, Michael Hucka, Thomas Morrell, and Ana Trisovic.

574 **Task Force on Best Practices for Software Registries participants:** Alain Mon-
575 teil, Alejandra Gonzalez-Beltran, Alexandros Ioannidis, Alice Allen, Allen Lee, An-
576 dre Jackson, Bryce Mecum, Caifan Du, Carly Robinson, Daniel Garijo, Daniel Katz,
577 Genevieve Milliken, Hervé Ménager, Jurriaan Spaaks, Katrina Fenlon, Kristin Van-
578 derbilt, Lorraine Hwang, Michael Hucka, Neil Chue Hong, P. Wesley Ryan, Peter
579 Teuben, Shelley Stall, Stephan Druskat, Ted Carnevale, Thomas Morrell.

580 **SciCodes Consortium participants:** Alain Monteil, Alejandra Gonzalez-Beltran,
581 Alexandros Ioannidis, Alice Allen, Allen Lee, Ana Trisovic, Anita Bandrowski, Bruce
582 Wilson, Bryce Mecum, Carly Robinson, Celine Sarr, Colin Smith, Daniel Garijo,

C RESOURCE INFORMATION

Since the first Task Force meeting was held in 2019, we have asked new resource representatives joining our community to provide the information shown in Table C.1. Thanks to this effort, the group has been able to learn about each resource, identify similarities and differences, and thus better inform our meeting discussions.

Table C.2, C.3 and C.4 provide an updated overview of the main features of all resources currently involved in the discussion and implementation of the best practices (30 resources in total as of December, 2021). Participating resources are diverse, and belong to a variety of discipline-specific (e.g. neurosciences, biology, geosciences,

1034 etc.) and domain generic repositories. Curated resources tend to have a lower number
 1035 of software entries. Most resources have been created in the last 20 years, with the
 1036 oldest resource dating from 1991. Most resources accept a software deposit, support
 1037 DOIs to identify their entries, are actively curated, and can be used to cite software.

Question	Answer type
Repository name and abbreviation	Text
Repository home page	URL
Representative name and email address	Text
Is the repository discipline-specific?	Yes/No
Is the repository for discipline software only?	Yes/No
Is a software deposit accepted?	Yes/No
Is a software deposit required?	Yes/No
Does your resource have a public scope/editorial policy?	URL
Supported unique identifier(s) type(s)	Text
Can the repository mint DOIs?	Yes/No
Is the repository actively curated?	Yes/No/Other
How are entries added?	Text
Is your resource currently used to cite software?	Yes/No/Other
When did your resource start operating?	Year started
What is the number of records (as of filling date)?	Integer
Notes/comments/additional information	Text

Table C.1. Questions asked to resource representatives.

Question	#Yes	#No	#Other
Is the resource discipline-specific?	18	12	0
Does the resource accept software only?	17	13	0
Does the resource require a software deposit?	5	25	0
Does the resource accept a software deposit	22	8	0
Can the resource mint DOIs?	16	14	0
Is the resource actively curated?	21	3	6
Can the resource be used to cite software?	21	6	3

Table C.2. Information shared by 30 resources participating in the SciCodes consortium, as of December 2021

#Entries	#Resources
Unknown	2
Less than 1K	15
1K - 100K	10
More than 100K	3

Table C.3. Number of entries described in the resources of the SciCodes consortium, by December 2021

Creation year	#Resources
Before 2000	6
2000 - 2010	9
After 2010	15

Table C.4. Date of creation of the resources in the SciCodes consortium, by December 2021
