ABSTRACT

Liver occupying lesions can profoundly impact an individual's health and well-being. To assist physicians in the diagnosis and treatment planning of abnormal areas in the liver, we propose a novel network named SEU²-Net by introducing the channel attention mechanism into U²-Net for accurate and automatic liver occupying lesion segmentation. We design the SE-RSU block, which is to add the SE attention mechanism at the residual connections of the RSU (the component unit of U²-Net). SEU²-Net not only retains the advantages of U²-Net in capturing context information at multiple scales, but also can adaptively recalibrate channel feature responses to emphasize useful feature information according to the channel attention mechanism. In addition, we present a new abdominal CT dataset for liver occupying lesion segmentation from Peking University First Hospital's clinical data (PUFH dataset). We evaluate the proposed method and compare it with five deep learning networks on the PUFH and LiTS dataset. The experimental results show that SEU²-Net has state-of-the-art performance and good robustness in liver occupying lesion segmentation.

INTRODUCTION

Liver occupying lesion segmentation is a significant research focus in the field of medical image analysis (Xue et al., 2021). It not only assists doctors in achieving more accurate analysis, diagnosis, and effective treatment planning for liver tumors (Li et al., 2018; Peng et al., 2022) but also fosters scientific research and technological innovation in the field of medical imaging (Li and Ma, 2022). The liver occupying lesion refer to various abnormal structures, tissues, or diseases that appear within the liver tissues, including liver tumors, liver cysts, liver abscesses, and so on. Most research papers on liver occupying lesion segmentation focus primarily on liver tumor segmentation. Liver tumor segmentation is divided into three methods based on gray scale segmentation algorithms, machine learning and deep learning. Based on gray scale segmentation algorithm: Qi et al. (Qi et al., 2008) proposed a semi-automatic segmentation method of CT liver tumor based on Bayesian rule 3D seed region growing (SRG). In the iterative updating process of region growing, Bayesian decision rules and model matching metrics are used as the growth criteria. This method had a good segmentation effect when the intensity difference between tumor and normal tissue is large, but there were large errors in the top and bottom slices in complex. Wong et al. (Wong et al., 2008) proposed a 2D region growing semi-automatic liver tumor segmentation method based on knowledge constraints. The segmentation effect was poor when the occupying lesion tissue and normal

45 liver tissue had low contrast.

46 Segmentation algorithm based on machine learning: Amita Das et al. (Das and Sabut, 2016) used
47 adaptive threshold, morphological processing and kernel fuzzy C-mean (KFCM) clustering algorithm
48 together with spatial information to segment liver tumor region. The segmented liver tumor image of this
49 method had high peak signal-to-noise ratio and low uniform error value. Munipraveena Rela et al. (Rela
50 et al., 2020) proposed superpixel-based fast fuzzy C-means clustering algorithm (SFFCM) for liver tumor
51 image segmentation to achieve an accuracy of 99.5 %. The segmentation algorithms based on machine
52 learning can only achieve good segmentation results on a single dataset but have no transfer ability.

53 The method based on deep learning realizes automatic liver tumor segmentation, which overcomes
54 the shortcomings of poor segmentation results when the contrast between tumor and normal liver tissue is
55 low in traditional segmentation algorithms. The method based on deep learning has the ability of transfer
56 learning. There are difficulties in making datasets and a relatively small number of datasets in liver tumor
57 image segmentation based on deep learning. However, the proposal of U-Net (Ronneberger et al., 2015)
58 solves the problem of fast training in a small number of data sets. Many improved models based on
59 U-Net have achieved good results in liver tumor segmentation. Liu et al. (Liu et al., 2019) improved
60 U-Net by increasing the depth of U-Net and only copying pooling layer features during skip-connection.
61 After that, use graph segmentation to optimize the segmentation results. The method smoothed the upper
62 boundary of liver tumor segmentation. Xu et al. (Xu et al., 2020) improved UNet++ and added the residual
63 structure in convolution blocks to avoid the problem of gradient disappearing. The method made the Dice
64 coefficient 93.36%. Seo et al. (Seo et al., 2019) improved the skip connection part of U-Net by adding
65 the residual path with deconvolution layer and activation operation. This method solved the repetition of
66 low-resolution feature information and had a good effect on the segmentation of liver tumor edge and
67 small structure. Li et al. (Li et al., 2020b) added an attention mechanism module to the convolution block
68 of UNet++. This method achieved good segmentation results in the LiTS dataset. However, the complex
69 structure led to slow training and prediction speed.

70 The deep learning methods discussed above have two main problems: on the one hand, some traditional
71 deep learning models such as UNet and SegNet. (Badrinarayanan et al., 2017) only use single-scale
72 feature maps for segmentation, which cannot effectively capture information at different scales. On the
73 other hand, when dealing with complex tumor contours and small tumors, the effect is not perfect. Other
74 models often have problems such as boundary blur and excessive smoothing, which make it difficult
75 to accurately segment complex tumor contours and small tumors. Based on these considerations, we
76 choose U²-Net (Qin et al., 2020) with multi-scale feature fusion and SE blocks with channel attention
77 mechanism.

78 We apply U²-Net to liver occupying lesion segmentation, which is a new attempt of U²-Net in the field
79 of medical image processing. In order to better segment small occupying lesion and complex occupying
80 lesion contours, the SE module is introduced into the U²-Net architecture (Li et al., 2020a; Gong et al.,
81 2022). The SE(Squeeze-and-Excitation) block (Hu et al., 2018) is a channel attention mechanism, which
82 can selectively emphasize informative features and suppress less useful ones by explicitly modeling
83 the interdependencies between their convolutional feature channels. Therefore, our model is termed
84 SEU²-Net. We propose an abdominal CT image dataset for liver occupying lesion segmentation from
85 Peking University First Hospital's clinical data (PUFH dataset). Use PUFH dataset and LiTS dataset to
86 train SEU²-Net model. By testing on the PUFH and LiTS dataset, prove the superiority of SEU²-Net
87 model in liver occupying lesion segmentation by comparing with different models. SEU²-Net obtains
88 *IoU* 90.86%, *Acc* 99.72%, *Kappa* coefficient 95.07%, *Dice* coefficient 95.21% on PUFH dataset and
89 *IoU* 80.81%, *Acc* 99.83%, *Kappa* coefficient 89.30%, *Dice* coefficient 89.39% on LiTS dataset.

90 MATERIALS AND METHODS

91 In this section, we design the architecture of SEU²-Net for liver occupying lesion segmentation to test
92 on the PUFH and LiTS dataset. The Biomedical Research Ethics Committee of Peking University First
93 Hospital approved the study of the PUFH dataset (Ethical Review No. 2020 Scientific Research 101
94 Amendments). The PUFH dataset did not require consent from study participants. Figure 1 shows
95 that SEU²-Net which is an encoder-decoder U-shaped structure consists of 11 SE-RSU structures with
96 different stages including six stages encoder and five stages decoder. The saliency map fusion module
97 is after the decoder levels and the last encoder level. The structure of SE-RSU is still a U-shaped
98 encoder-decoder structure. Compared to the architecture of U²-Net, our innovation is SE-RSU that adds

99 the channel attention mechanism SE block at the residual connection of RSU. In SEU²-Net, a mix of
 100 CrossEntropyLoss() and DiceLoss() loss functions is used instead of the standard binary cross-entropy
 101 loss function used in the U²-Net paper. The hybrid use of the above two loss functions can optimize the
 102 prediction accuracy, prediction accuracy and model robustness of liver occupying lesion segmentation.

103 SEU²-Net has the attention mechanism and multi-scale feature fusion strategy. For the attention
 104 mechanism: SEU²-Net employs an attention mechanism using SE blocks to adaptively weight the channel
 105 features, allowing the model to focus on important feature information. The SE block mainly includes the
 106 global pooling and sigmoid activation functions. Then, the two operations of scale and residual are used to
 107 emphasize the occupying lesion information in liver occupying lesion segmentation, especially the small
 108 occupying lesion and complex occupying lesion contour.

109 For multi-scale feature fusion strategy: Firstly, the SEU²-Net model adopts multi-scale images input in
 110 the encoder. Specifically, it scales the original image to different scales by a certain proportion, and inputs
 111 the scaled image into the model for feature extraction and segmentation prediction, whose advantage is
 112 that the image features at different scales can be effectively extracted, and the cross-layer fusion between
 113 the features at different scales can be performed to further improve the accuracy and robustness of the
 114 model. In the decoder, for each decoder layer, SEU²-Net will obtain the feature map of the corresponding
 115 scale from the encoder, and fuse it into the feature map of the current layer through upsampling and
 116 deconvolution operations. The feature information of different scales can be used to improve the detection
 and segmentation ability of the model for objects.

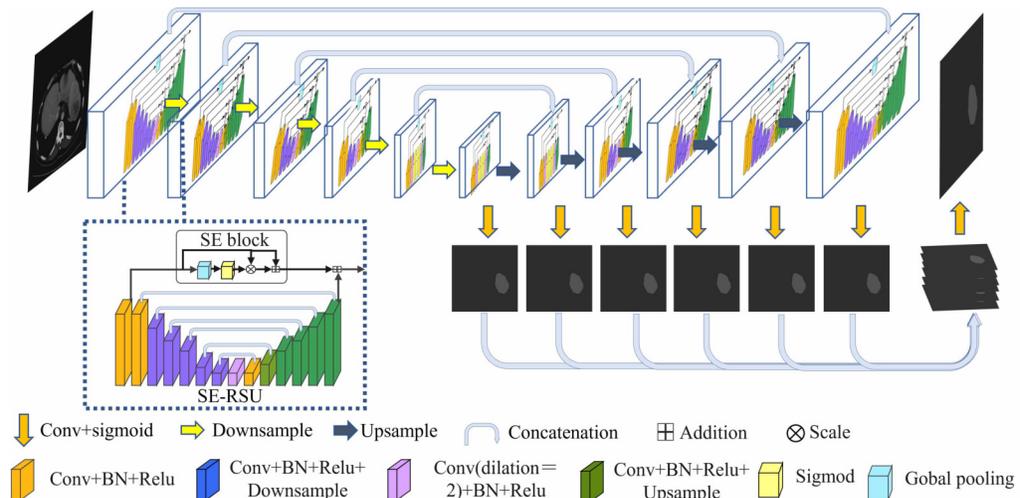

Figure 1. The architecture of SEU²-Net. SEU²-Net consists of 11 SE-RSU structures and multi-scale fusion operations. SE-RSU integrates SE attention mechanism into the residual connection of RSU. The input image is a 512×512 abdominal CT slice, and the output image is a 512×512 segmented liver occupying lesion image. (a) SEU²-Net employs a multi-scale feature fusion strategy to enhance its detection and segmentation capabilities by utilizing feature information from different scales. (b) SEU²-Net utilizes SE blocks as attention mechanism to adaptively weight channel features, allowing the model to focus on important feature information.

117

118 SE Residual U-blocks

119 SE-RSU (Residual U-block with Squeeze-and-Excitation) is a new structure introduced in U²-Net, which
 120 incorporates the Squeeze-and-Excitation (SE) mechanism into the Residual U-block (RSU) of U²-Net.
 121 The SE Residual U-blocks (SE-RSU) terms that the SE block is added to the position of the residual
 122 connection in the RSU. The SE block is an attention mechanism used to enhance the model's feature
 123 representation capability by adaptively learning the correlations between feature channels to better capture
 124 important feature information. The purpose of adding SE after the first convolutional block of SE-RSU
 125 is coarse-grained context detection in the initial layer network and fine-grained context detection in the
 126 deep network as SE-RSU goes deeper in the SEU²-Net network. Figure 2 shows that the SE block is
 127 implemented by passing the output of the convolution operation through a Global Pooling layer, and then

128 normalizing it using a Sigmoid function in SE-RSU. Firstly, global spatial information compression into
 129 channel descriptors is achieved by using global average pooling to generate channel statistics. i.e., the
 130 size $H \times W \times C$ feature is compressed to $1 \times 1 \times C$. Then, the sigmoid activation function is used to learn
 131 nonlinear interactions between channels to capture channel dependencies. The output of sigmoid function
 132 is channel-multiplied with the original feature to highlight the useful feature information and ignore the
 133 less useful ones. Finally, residual connection in the SE block is used to avoid gradient vanishing.

134 Compared to other papers(Tian et al., 2021; Zhang et al., 2022; Fan et al., 2021; Zhang and Zhang,
 135 2021), the SE block in our paper only includes global average pooling and sigmoid activation function,
 136 without fully connected layers. The role of fully connected layers is to map the feature vector after global
 137 pooling to a lower-dimensional vector. However, the SE block is connected to the first convolutional layer
 138 of the SE-RSU, where the shallow convolutional layer and feature extraction result in a smaller depth
 139 of the feature map. Using global average pooling and sigmoid activation function directly for feature
 140 fusion can meet the demand for adaptive weighting of channel features. On the other hand, not using
 141 fully connected layers reduces the number of model parameters and computational complexity, preventing
 overfitting of the model.

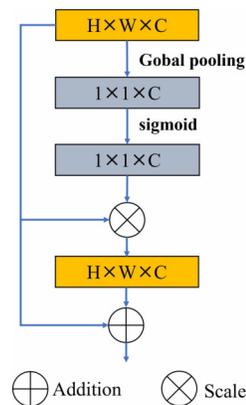

Figure 2. The SE block. The SE block includes global pooling and sigmoid activation operations, which is added to the residual connection of the SE-RSU.

142

143 Loss functions

144 Compared to the U²-Net paper which uses the standard binary cross-entropy loss function, we use a
 145 combination of CrossEntropyLoss() and DiceLoss() in our approach. The DiceLoss() function is primarily
 146 used to optimize the model's prediction accuracy and robustness, particularly for enhancing the prediction
 147 precision and robustness of the model. DiceLoss() is used to optimize the model's prediction precision and
 148 robustness. By using these two loss functions together, the model can find a balance between accuracy and
 149 precision and has better generalization ability. However, the binary cross entropy loss function is sensitive
 150 to pixel class distribution imbalance, which can cause the model's prediction results to be biased towards
 151 regions with more pixel classes, and can result in misclassification in regions with fewer pixel classes.
 152 Additionally, the binary cross entropy loss function cannot handle the problem of target boundaries well,
 153 which can lead to prediction results with breaks or blur at the boundaries, affecting the segmentation
 154 performance of the model. Therefore, the binary cross entropy loss function is not effective for small or
 155 complex occupying lesion contours in liver occupying lesion segmentation.

Choose to use a mix of CrossEntropyLoss() and DiceLoss() loss functions with corresponding weights
 of 0.7 and 0.3. Equation 1 is the loss function expression of CrossEntropyLoss(). N represents the
 number of samples, C represents the number of classes, y_{ij} represents the j -th label of i -th sample, and
 p_{ij} represents the predicted probability of the j -th class for i -th sample. The cross-entropy loss function
 measures how close the predicted value is to the ground truth.

$$CrossEntropyLoss() = -\frac{1}{N} \sum_{i=1}^N \sum_{j=1}^C y_{ij} * \log(p_{ij}) \quad (1)$$

Equation 2 is the expression of the loss function for DiceLoss(), where Dice is given by Equation 6. DiceLoss() is used when the background area is much larger than the target area. Because the liver occupying lesion area is smaller than the liver background area, DiceLoss() will have a better effect.

$$DiceLoss() = 1 - \frac{|A \cap B|}{|A| + |B|} \quad (2)$$

156 Evaluation Metrics

Iou refers to the ratio between the intersection and union of the true value and the predicted value in a class. The formula is as shown in equation 3. In our paper, *TP* represents the intersection of the predicted liver occupying lesion and labeled occupying lesion. $TP + FP + FN$ represents the union of the predicted liver occupying lesion and labeled occupying lesion.

$$Iou = \frac{TP}{TP + FP + FN} \quad (3)$$

Acc(Accuracy) is the overall classification accuracy, which is the probability of predicting the correct number of samples over the total number of samples. *Acc* can be expressed in equation 4 using confusion matrices. *intersect_area* represents the intersection area of prediction and ground truth on all classes. All classes in the experiment refers to the liver space-occupying lesion and background. *pred_area* represents the prediction area on all classes.

$$Acc = \frac{intersect_area}{pred_area} \quad (4)$$

The *Kappa* coefficient measures the effect of whether the predicted value is consistent with the actual classification value. The *Kappa* coefficient compensates for the bias towards large categories in *Acc* caused by the gap in the number of categories. Equation 5 is the calculation method of *Kappa* coefficient, where P_e represents the ratio of the product of the number of true categories and the number of corresponding predicted categories to the square of the total number of samples. A *Kappa* coefficient between 0.81 and 1 indicates almost perfect agreement.

$$Kappa = \frac{Acc - P_e}{1 - P_e} \quad (5)$$

The *Dice* coefficient represents the proportion of duplicate parts between the predicted segmented image and the annotated image. *Dice* has a value between 0 and 1. In equation 6, *A* represents the pixel value of the true image and *B* represents the pixel value of the predicted image.

$$Dice = \frac{|A \cap B|}{|A| + |B|} \quad (6)$$

157 Process of experiment

The datasets were divided into training set, test set and verification set in a ratio of 8:1:1. Mix CrossEntropyLoss() and DiceLoss() loss functions. The Momentum optimizer which contains the Newtonian momentum flag can better eliminate the wobble phenomenon in the process of updating the hyperparameter. Use Cosine annealing methods to dynamically adjust the learning rate shown in equation 7.

$$\eta_t = \eta_{min}^i + \frac{1}{2}(\eta_{max}^i - \eta_{min}^i)(1 + \cos \frac{T_{cur}\pi}{T_i}) \quad (7)$$

158 Let *i* denote the number of learning rate changes at the i, h time. The initial learning rate η_{max}^i is
 159 0.0015. The minimum learning rate η_{min}^i is 0. T_{cur} is the current epoch. T_i is the number of iterations in
 160 one learning rate cycle, which is set to 5400. The batch size is 4. The model is saved every 900 training
 161 runs, for a total of 9000 training runs. The experiments are trained on NVIDIA Tesla V100 GPU(32GB).

162 RESULTS

163 PUFH dataset

164 dataset setup

165 The PUFH dataset consisted of 200 3D abdominal CT images and corresponding labeled images, which
166 labeled various types of liver occupying lesions such as hepatic cysts, liver abscess, and hepatocellular
167 carcinoma. The number of slices that can be scanned at a time ranges from 39 to 107 depending on the
168 information of each 3D image when the dataset is sliced horizontally. The resolution of slice images
169 ranged from [0.5839844, 0.5839844, 5.0] to [0.88671875, 0.88671875, 5.0]mm, and the image intensity
170 ranges from [-1024.0, 3071.0] to [-3024.0, 1210.0]. The slice size is 512×512 . Figure 3 shows the fusion
171 slice image of a random abdominal CT image and its corresponding annotated image in the PUFH dataset.

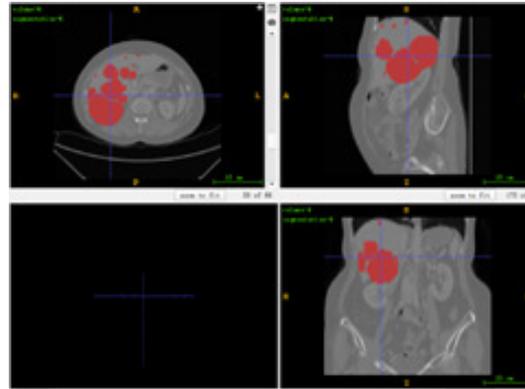

Figure 3. A random fusion image from PUFH dataset.

172

173 dataset processing

174 The dataset is abdominal CT data containing multiple organs. In order to ensure the accuracy of model
175 training, find the slice data of the original image from the beginning to the end of the liver according to
176 the labeled image data. The Nii format data containing only the liver region is converted into 2D data in
177 PNG format, and the size of the converted 2D data is 512×512 .

178 Experimental results

179 The training results of U-Net, AttentionU-Net(Oktay et al., 2018), UNet3Plus(Huang et al., 2020)
180 ,UNetPlusPlus(Zhou et al., 2020) and U²-Net are compared with SEU²-Net in the PUFH dataset. Table 1
181 shows the evaluation metrics of PUFH dataset in five models. SEU²-Net outperforms for liver CT image
182 segmentation in five methods, achieving the *IoU* ratio increased 0.75%, the *Acc* increased 0.04%, the
183 *Kappa* coefficient increased 0.44%, the *Dice* coefficient increased by 0.41% over U²-Net. Compared
184 with AttentionU-Net, which is the combination of attention mechanism and UNet, SEU²-Net had the
185 highest improvement, among which the *Iou* ratio increased by 8.8%, the *Acc* increased by 0.36%, the
186 *Kappa* coefficient increased by 5.26% and the *Dice* coefficient increased by 5.07%. Figure 4 shows that
187 Six 2D slices are randomly selected in the dataset to observe the liver occupying lesion segmentation
188 effect of the five models. The effect of liver occupying lesion segmentation depends on the location
189 of segmentation, the overall contour and the recognition of small liver occupying lesion. SEU²-Net is
190 most similar to label in terms of the location and size of liver occupying lesion. For example, the liver
191 occupying lesion in the fifth slice has complex contours and fine regions. Comparing the segmentation
192 effects of the six models in the fifth slice, SEU²-Net can identify very small liver occupying lesion and
193 complex edges (the mark of the red box), which greatly illustrates the importance of SEU²-Net's attention
194 mechanism and its ability to capture feature information from multiple scales perspectives.

195 LiTS dataset

196 dataset setup and processing

197 As liver tumors are among the different types of liver occupying lesions, the LiTS dataset consists of 131
198 contrast-enhanced 3D abdominal CT scans, including 70 scans for training and testing with corresponding

| | IoU(%) | Acc(%) | Kappa(%) | Dice(%) |
|-----------------------|--------------|--------------|--------------|--------------|
| U-Net | 86.85 | 99.54 | 92.72 | 92.96 |
| AttentionU-Net | 82.06 | 99.36 | 89.81 | 90.14 |
| UNet3Plus | 65.10 | 98.53 | 78.10 | 78.86 |
| UNetPlusPlus | 81.92 | 99.42 | 89.76 | 90.06 |
| U ² -Net | 90.11 | 99.68 | 94.63 | 94.80 |
| SEU ² -Net | 90.86 | 99.72 | 95.07 | 95.21 |

Table 1. Evaluation metrics table of PUFH dataset

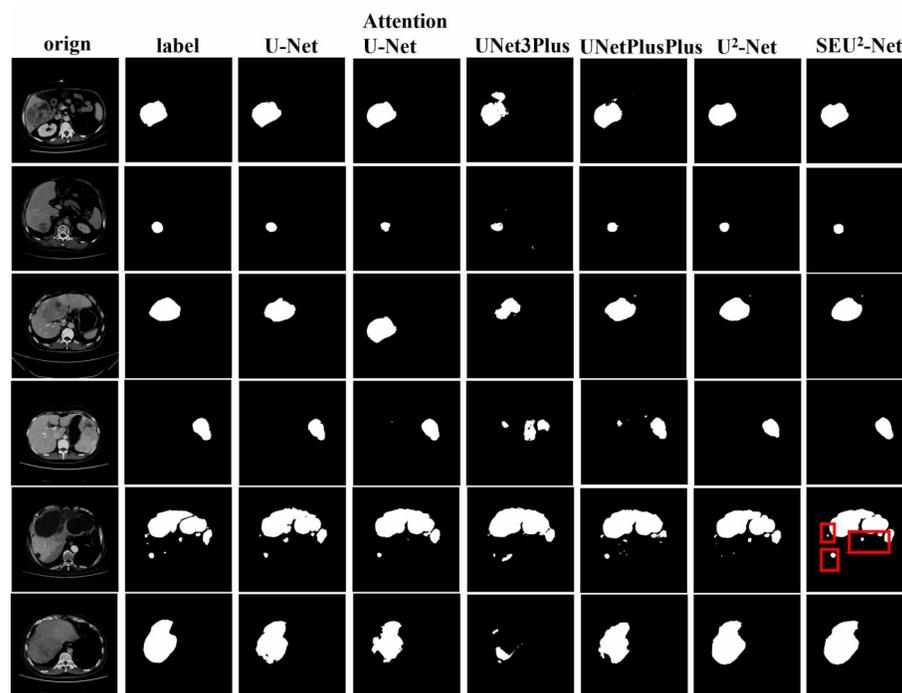

Figure 4. Liver occupying lesion segmentation of PUFH dataset. Column 1: Origin. Column 2: Label. Column 3: U-Net. Column 4: AttentionU-Net. Column 5: UNet3Plus. Column 6: UNetPlusPlus. Column 7: U²-Net. Column 8: SEU²-Net.

199 annotated images specifically focusing on liver occupying lesion segmentation. The number of tumors
 200 varied from 0 to 75, and the size varied from $38mm^3$ to $349mm^3$. The layer spacing (section thickness) is
 201 $[0.45,6]mm$. The number of slices that can be scanned at a time ranges from 42 to 1026 according to the
 202 different information of each 3D image. The size of 2D slices is 512×512 , where the planar resolution is
 203 $[0.6 \times 0.6, 1.0 \times 1.0]mm$.

204 For the processing of the LiTS dataset, only the tumor label is retained during liver tumor segmentation
 205 because the dataset contained both liver and tumor labels. Then the processing of the dataset is the same
 206 as that of the PUFH dataset. Figure 5 shows the fusion slice image of a random abdominal CT image and
 207 its corresponding annotated image in the LiTS dataset.

208 **Experimental results**

209 The six models trained on the PUFH dataset are used for training and testing in the Lits dataset. The
 210 evaluation metrics of LiTS dataset are shown in Table 2. Compared with U²-Net, SEU²-Net has the *Iou*
 211 increased by 0.14%, *Kappa* coefficient increased by 0.09%, and *Dice* coefficient increased by 0.09% in the
 212 four evaluation metrics. UNet3Plus performs the worst among the four evaluation metrics. Compared with
 213 UNet3Plus, the *Iou* of SEU²-Net is increased by 17.55%, *Acc* is increased by 0.2%, *Kappa* coefficient
 214 is increased by 11.99%, and *Dice* coefficient is increased by 11.90%. At the same time, the evaluation
 215 metrics of SEU²-Net on LITS dataset are still higher than those of AttentionU-Net. Figure 6 shows that

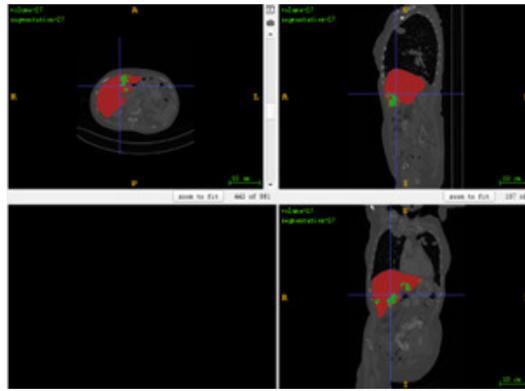

Figure 5. A random fusion image from LiTS dataset.

216 randomly select six 2D slices in the LiTS dataset to observe the liver tumor segmentation effect of the five
 217 models. Most of liver tumors in these 6 pictures are small, and SEU²-Net is most similar to label in terms
 218 of the location and size of liver tumors, which proves that SEU²-Net has advantages in the segmentation
 of small tumors.

| | IoU(%) | Acc(%) | Kappa(%) | Dice(%) |
|-----------------------|--------------|--------------|--------------|--------------|
| U-Net | 75.57 | 99.78 | 85.98 | 86.08 |
| AttentionU-Net | 75.98 | 99.78 | 86.24 | 86.35 |
| UNet3Plus | 63.26 | 99.63 | 77.31 | 77.49 |
| UNetPlusPlus | 73.46 | 99.75 | 84.57 | 84.70 |
| U ² -Net | 80.67 | 99.83 | 89.21 | 89.30 |
| SEU ² -Net | 80.81 | 99.83 | 89.30 | 89.39 |

219

220 DISCUSSION

221 Automatic segmentation of liver occupying lesion plays an important role in the clinical diagnosis and
 222 treatment of liver diseases. Accurate location and size of liver occupying lesion it provides greatly
 223 improves the efficiency of diagnosis. In this paper, we propose the SEU²-Net deep learning model,
 224 which adds the SE block with channel attention mechanism to the U²-Net model that can capture
 225 context information from multiple scales. In order to verify the robustness of SEU²-Net and its superior
 226 performance in liver occupying lesion segmentation, we use SEU²-Net model to train and test on the
 227 PUFH and LiTS dataset. Compared to U-Net, AttentionU-Net, UNet3Plus, UNetPlusPlus and U²-Net,
 228 table 1 and table 2 show that SEU²-Net achieved superior results in terms of *IoU*, *Acc*, *Kappa* coefficient
 229 and *Dice* coefficient, indicating that SEU²-Net can more accurately locate and segment liver lesions in
 230 the liver occupying lesion segmentation task, while maintaining low error and misclassification rates.
 231 Specifically, the improvement of SEU²-Net compared to U²-Net is mainly concentrated in terms of
 232 accuracy and stability, which suggests that the success of SEU²-Net is closely related to the performance
 233 of the SE block. Figure 4 and figure 6 show that SEU²-Net performs very well in segmenting small and
 234 complex liver occupying lesion, which can be attributed to the powerful characteristics of the SE block.
 235 The SE block can adaptively adjust the weights of each channel in the feature map to better capture features
 236 at different levels. When segmenting small and complex liver lesions, the model requires higher resolution
 237 and better feature expression ability, and the introduction of the SE block can effectively improve the
 238 feature expression ability of the model, thereby capturing these tiny yet important details. Therefore,
 239 SEU²-Net performs better in the segmentation of small and complex liver occupying lesion. At the same
 240 time, by introducing the SE block, the model can better avoid overfitting, improve its generalization
 241 ability, and make its performance more stable and reliable on different datasets.

242 SEU²-Net performs differently on two datasets. It shows excellent performance on the PUFH dataset,
 243 achieving high *IoU*, *Acc*, *Kappa* coefficient, and *Dice* coefficient. However, its performance on the LiTS

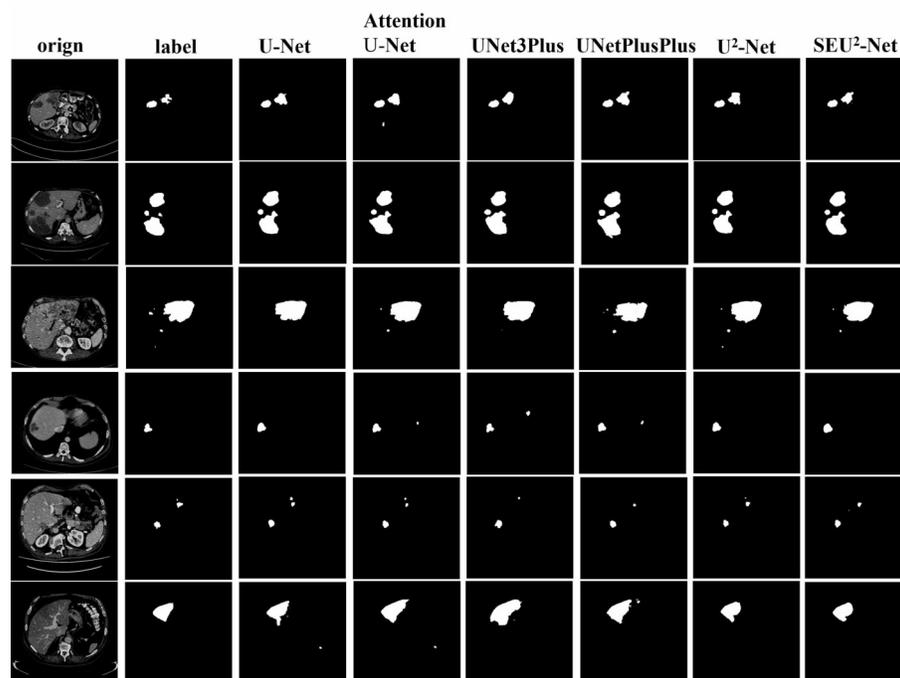

Figure 6. Liver occupying lesion segmentation of LiTS dataset. Column 1: Origin. Column 2: Label. Column 3: U-Net. Column 4: AttentionU-Net. Column 5: UNet3Plus. Column 6: UNetPlusPlus. Column 7: U²-Net. Column 8: SEU²-Net.

244 dataset is relatively lower. This may be due to the differences in characteristics and backgrounds between
 245 the two datasets. The PUFH dataset includes various liver occupying lesion such as liver tumors, liver
 246 cysts, and liver abscesses, which have relatively obvious shape and texture features, making them easier to
 247 be captured and distinguished by the model. On the other hand, the liver lesions in the LiTS dataset only
 248 include liver tumors, some of which have very small volumes and may be affected by randomness and
 249 noise interference, leading to a slight decrease in the model's performance on the LiTS dataset. Overall,
 250 SEU²-Net's performance on the LiTS dataset is relatively poor, indicating that there is still room for
 251 improvement in SEU2Net's generalization ability when handling complex datasets.

252 Although SEU²-Net performs well, there are still some limitations in this study. One limitation is
 253 that the dataset used only focuses on liver occupying lesions. Therefore, it is necessary to evaluate the
 254 performance of SEU²-Net on larger and more diverse datasets in future research. Another limitation is that
 255 we have not conducted a thorough analysis to assess the contribution of the SE block to the performance
 256 of SEU2Net. In the future, we plan to study the effects of different SE block configurations and compare
 257 them with other attention mechanisms such as CBAM(Woo et al., 2018) and BAM(Park et al., 2018).

258 CONCLUSIONS

259 Our paper propose a network architecture called SEU²-Net based on improved U²-Net for liver occupying
 260 lesion segmentation. SEU²-Net combines the SE block and U²-Net, which retains the ability of U²-Net to
 261 capture context information at multiple scales, and emphasizes useful information and ignores useless
 262 information through the channel attention mechanism. In addition, we present a new liver occupying
 263 lesion CT dataset from Peking University First Hospital's clinical data (PUFH dataset). SEU²-Net is
 264 compared with U-Net, AttentionU-Net, UNet3Plus ,UNetPlusPlus and U²-Net for liver occupying lesion
 265 segmentation on LiTS and PUFH datasets. The *Iou*, *Acc*, *Kappa* coefficient and *Dice* coefficient of SEU²-
 266 Net are 90.86%, 99.72%, 95.07%, 95.21% and 80.81%, 99.83%, 89.30%, 89.39% on PUFH and LiTS
 267 datasets. The experiment shows that SEU²-Net with attention mechanism outperforms AttentionU-Net
 268 with attention mechanism. SEU²-Net can predict small liver occupying lesion and complex contours
 269 from the liver occupying lesion segmentation images of the two datasets. Compared with the other five
 270 U-Net series networks, the accuracy, repeatability and consistency between the liver occupying lesion

271 segmentation images predicted by SEU²-Net and the label images are the best. Our proposed method is
272 an attempt of U²-Net in the field of medical image processing. The superior performance of SEU²-Net
273 with attention mechanism in liver occupying lesion segmentation indicates that it has good development
274 potential in the field of medical image processing.
