Brain tumors present a significant medical challenge, demanding accurate and timely diagnosis for effective treatment planning. These tumors disrupt normal brain functions in various ways, giving rise to a broad spectrum of physical, cognitive, and emotional challenges. The daily increase in mortality rates attributed to brain tumors underscores the urgency of this issue. In recent years, advanced medical imaging techniques, particularly Magnetic Resonance Imaging (MRI), have emerged as indispensable tools for diagnosing brain tumors. Brain MRI scans provide high-resolution, non-invasive visualization of brain structures, facilitating the precise detection of abnormalities such as tumors. This study aims to propose an effective neural network approach for the timely diagnosis of brain tumors. Our experiments utilized a multi-class MRI image dataset comprising 21,672 images related to glioma tumors, meningioma tumors, and pituitary tumors. We introduced a novel neural network-based feature engineering approach, combining 2D Convolutional Neural Network (2DCNN) and VGG16. The resulting 2DCNN-VGG16 network (CVG-Net) extracted spatial features from MRI images using 2DCNN and VGG16 without human intervention. The newly created hybrid feature set is then input into machine learning models to diagnose brain tumors. We have balanced the multi-class MRI image features data using the Synthetic Minority Over-sampling Technique (SMOTE) approach. Extensive research experiments demonstrate that utilizing the proposed CVG-Net, the k-neighbors classifier outperformed state-of-the-art studies with a k-fold accuracy performance score of 0.96. We also applied hyperparameter tuning to enhance performance for multi-class brain tumor diagnosis. Our novel proposed approach has the potential to revolutionize early brain tumor diagnosis, providing medical professionals with a cost-effective and timely diagnostic mechanism.

ABSTRACT

Brain tumors present a significant medical challenge, demanding accurate and timely diagnosis for effective treatment planning. These tumors disrupt normal brain functions in various ways, giving rise to a broad spectrum of physical, cognitive, and emotional challenges. The daily increase in mortality rates attributed to brain tumors underscores the urgency of this issue. In recent years, advanced medical imaging techniques, particularly Magnetic Resonance Imaging (MRI), have emerged as indispensable tools for diagnosing brain tumors. Brain MRI scans provide high-resolution, non-invasive visualization of brain structures, facilitating the precise detection of abnormalities such as tumors. This study aims to propose an effective neural network approach for the timely diagnosis of brain tumors. Our experiments utilized a multi-class MRI image dataset comprising 21,672 images related to glioma tumors, meningioma tumors, and pituitary tumors. We introduced a novel neural network-based feature engineering approach, combining 2D Convolutional Neural Network (2DCNN) and VGG16. The resulting 2DCNN-VGG16 network (CVG-Net) extracted spatial features from MRI images using 2DCNN and VGG16 without human intervention. The newly created hybrid feature set is then input into machine learning models to diagnose brain tumors. We have balanced the multi-class MRI image features data using the Synthetic Minority Over-sampling Technique (SMOTE) approach. Extensive research experiments demonstrate that utilizing the proposed CVG-Net, the k-neighbors classifier outperformed state-of-the-art studies with a k-fold accuracy performance score of 0.96. We also applied hyperparameter tuning to enhance performance for multi-class brain tumor diagnosis. Our novel proposed approach has the potential to revolutionize early brain tumor diagnosis, providing medical professionals with a cost-effective and timely diagnostic mechanism.

1 INTRODUCTION

Brain tumors are abnormal growths of cells within the brain that can disrupt normal brain function and pose serious health risks Miao et al. (2023). Detecting and diagnosing brain tumors is paramount for timely intervention and treatment. MRI brain scans have become a crucial tool Zhu et al. (2023). MRI scans utilize powerful magnets and radio waves to generate detailed images of the brain structure, allowing

healthcare professionals to visualize abnormalities Liu et al. (2023b). The MRI scans are especially effective in identifying brain tumors because they provide high-resolution images that can differentiate between healthy brain tissue and tumor masses.

Brain tumors can be classified into various types, each with its distinct characteristics and potential challenges in diagnosis and treatment Mehnatkesh et al. (2023); Liu et al. (2023a). Glioma tumors originate in the glial cells, which provide support and protection to neurons Oztek et al. (2023). They are often classified according to their aggressiveness, with high-grade gliomas being particularly concerning due to their rapid growth and infiltrative nature. On the other hand, Meningioma tumors develop from the meninges, the protective membranes surrounding the brain and spinal cord. While often benign, they can cause symptoms by compressing nearby brain structures Bhatele and Bhadauria (2023). Pituitary tumors, which arise in the pituitary gland located at the base of the brain, can affect hormone production and regulation, leading to a wide range of health issues.

The mortality rates caused by brain tumors are increasing daily. Between 2014 and 2018, the average annual age-adjusted incidence rate for primary malignant brain tumors was 7.06 per 100,000 individuals. Projections indicated that in 2022, an estimated 25,050 new diagnoses and 18,280 fatalities would be attributed to primary malignant brain tumors Thierheimer et al. (2023). Brain tumors were 24.25 per 100,000 individuals, comprising 7.06 per 100,000 for malignant cases and 17.18 per 100,000 for non-malignant cases Li et al. (2023a). Similarly, based on the 2018 data from the Global Cancer Registry, a total of 18,078,957 cancer cases were reported across all genders, with 29,681 cases attributed to brain cancer Khazaei et al. (2020).

Traditional diagnostic methods for brain tumors have primarily relied on radiological imaging techniques such as computed tomography (CT) Zhang et al. (2023) and MRI. Classical treatment modalities for brain tumors encompass surgical resection, radiation therapy, and chemotherapy, with the specific approach chosen depending on tumor type, location, and patient characteristics. Deep learning based methods use MRI images analyzed using convolutional neural networks (CNN) for brain tumor recognition Rajinikanth et al. (2021, 2022); Maqsood et al. (2021, 2022); Badjie and Deniz Ülker (2022); Kurdi et al. (2023); Khan et al. (2023).

In this study, we propose an advanced image-processing mechanism that effectively diagnoses brain tumors without human intervention. We introduce a novel neural network, CVG-Net, for transfer learning-based spatial feature extraction from MRI images. These newly created transfer features are then employed to diagnose brain tumors using machine learning models.

Our contributions regarding brain tumor diagnosis are as follows:

- We have introduced a novel neural network method, CVG-Net, for feature engineering. This method combines 2DCNN and VGG16 to extract spatial features from MRI images. The resulting hybrid spatial feature set is input into machine learning models to diagnose brain tumors.
- We employed the SMOTE technique to balance the multi-class MRI image feature data, resulting in more accurate and reliable diagnoses of brain tumors. This approach addresses class imbalance issues within medical image analysis.
- We utilized four advanced machine learning models and two deep learning models based on neural networks for comparative performance evaluations. Each method's performance is optimized through hyperparameter tuning and validated using k-fold cross-validation. Additionally, we calculated the computational complexity of each method for diagnosing brain tumors.

The rest of the study is organized as follows: Section 2 analyzes the limitations in previous literature. Section 3 demonstrates our proposed research methodology for diagnosing brain tumors. Section 4 comparatively evaluates the results of the applied neural network approaches. Our findings are concluded in Section 5.

2 LITERATURE ANALYSIS

This literature analysis section comprehensively examines existing studies and methodologies related to both neural network applications in medical imaging and transfer learning techniques. It delves into the foundational work in medical image analysis, emphasizing the pivotal role of neural networks in automating the detection and diagnosis of various pathologies, including brain tumors. Additionally, it

synthesizes the key findings and methodologies from relevant studies, providing a robust foundation for the subsequent implementation of transfer learning techniques in the proposed diagnosis framework for brain tumors using MRI scans.

This study Archana et al. (2023) introduces a comparative analysis of several optimizers employed in Convolutional Neural Networks (CNNs) for the purpose of brain tumor detection. Within Deep Learning (DL), Artificial Neural Networks (ANNs) play a crucial role in discerning brain tumors. The medical image dataset is employed for applied methods training and evaluation. Among the various approaches investigated, the application of the AlexNet architecture in conjunction with the Stochastic Gradient Descent (SGD) optimizer demonstrated superior performance. This proposed approach achieved a diagnostic accuracy of 0.80.

The author of this Sudharson et al. (2022) study proposed a hybrid deep learning-based neural system for the detection of brain tumors. The study introduced fundamental concepts of image separation to address the challenges associated with partitioning brain MRI images. Various MRI pre-processing techniques were then elaborated, encompassing tasks such as image registration, bias field correction, and non-brain tissue removal. Additionally, the author presented a Hybrid CNN-based partitioning approach, which proved advantageous for delineating brainstem tumors in MRI scans when augmented with prior knowledge. The proposed approach demonstrated an accuracy score of 0.93.

This article Sharif et al. (2020) introduces a novel approach to actively employ deep learning for the segmentation and recognition of brain tumors in MRI images. The authors utilize the pre-trained Inception V3 Convolutional Neural Network (CNN) model for robust deep feature extraction during the classification phase. These features are integrated with the dominant rotated Local Binary Pattern (DRLBP) to enhance texture analysis. Subsequently, a particle swarm optimization (PSO) technique is employed to fine-tune the concatenated feature vector for classification using a softmax classifier. The study is conducted in two phases. In the initial phase, the segmentation approach (SbDL) is validated on BRATS2017 and BRATS2018 datasets, demonstrating promising Dice scores. For instance, the BRATS2017 dataset achieves Dice scores of 83.73% for the core tumor, 93.7% for the whole tumor, and 79.94% for the enhanced tumor. Moreover, the BRATS2018 dataset attains a Dice score of 88.34%. In the subsequent phase, the classification strategy is applied to BRATS2013, 2014, 2017, and 2018 datasets, yielding an average accuracy of over 92%.

The study Kibriya et al. (2022) is focused on developing an automated method for precise brain cancer identification through tumor diagnosis. Previous systems have struggled with issues related to subpar accuracy and high false-positive rates. To address this, the study introduces a pioneering 13-layer CNN architecture specifically designed for classifying brain tumors from MRI scans. The effectiveness of the proposed model was assessed using a standardized dataset comprising 3064 MRI images encompassing three distinct categories of brain cancer: glioma, pituitary, and meningioma. The results demonstrated an average accuracy of 97%.

The study Yazdan et al. (2022) introduces an innovative approach to diagnosing brain tumors. It employs a dual-pronged strategy, utilizing a Multi-Scale CNN (MSCNN) architecture to develop a robust classification model, while also addressing the impact of Rician noise on MSCNN performance. This model enables the multi-classification of MRIs, distinguishing between glioma, meningioma, pituitary, and non-tumor cases. Additionally, a denoising process is implemented using a Fuzzy Similarity-based Non-Local Means (FSNLM) filter to enhance classification results. The study utilizes an openly accessible MRI dataset comprising 3264 MRIs. Experimental results demonstrate that the proposed MSCNN model outperforms both AlexNet and ResNet, exhibiting superior accuracy and efficiency while incurring lower computational expenses. Specifically, the MCNN2 iteration achieves an impressive accuracy and F1-score of 91.2% and 91%, respectively.

The study Stadlbauer et al. (2022) investigates the potential of employing multiclass machine learning (ML) algorithms on an extensive array of radiomic features derived from advanced MRI (advMRI) and physiological MRI (phyMRI) data. This innovative methodology, referred to as radiophysiomics, aims to achieve precise classification of contrast-enhancing brain tumors. The study leveraged a substantial MRI database, encompassing more than 1700 MR examinations of brain tumor patients, for the purpose of model development. The findings revealed that the application of Adaptive Boosting and Random Forest algorithms in conjunction with both advMRI and phyMRI data surpassed human reading in various performance metrics, including accuracy (0.875 vs. 0.850), precision (0.862 vs. 0.798), and F-score (0.774 vs. 0.740). Nevertheless, it was observed that radiologists demonstrated higher sensitivity (0.767

152 vs. 0.750) and specificity (0.925 vs. 0.902) compared to the machine learning models.

153 The study Fabelo et al. (2019) introduces a novel framework centered on deep learning techniques,
154 tailored for the analysis of hyperspectral images depicting live human brain tissue. Through rigorous
155 evaluation using a diverse database of 26 in vivo hyperspectral cubes from 16 individual patients,
156 encompassing a total of 258,810 annotated pixels, the framework proves adept at generating a thematic
157 representation that delineates the brain's parenchymal area and accurately identifies the tumor's position.
158 This information serves as a crucial aid to surgeons, significantly enhancing the precision of tumor
159 resection procedures. Notably, the deep learning pipeline 2D convolutional neural network exhibits an
160 impressive overall accuracy of 80% for multiclass classification, which is low compared to baseline.

161 The study Latif et al. (2022) introduces an innovative method for categorizing Glioma tumors, utilizing
162 features based on deep learning in conjunction with a Support Vector Machine (SVM) classifier. Through
163 the application of a deep convolutional neural network for feature extraction from MR images sourced
164 from the BraTS dataset, the study achieved noteworthy levels of accuracy in classification. Specifically,
165 an accuracy of 96.19% was observed for the HGG Glioma type using the FLAIR modality, and a
166 commendable accuracy of 95.46% was obtained for the LGG Glioma tumor type when employing the T2
167 modality. Notably, this method encompassed the classification of four distinct Glioma classes, including
168 Edema, Necrosis, Enhancing, and Non-enhancing. This pioneering approach shows promising potential
169 in the domain of Glioma tumor classification.

170 The analyzed works with their research limitations are summarized in Table 3.

Table 1. The literature summary and limitations analysis.

Ref	Dataset	Proposed Tech- nique	Performance Accuracy	Research Limitations
Archana et al. (2023)	Brain tumours medi- cal images	AlexNet with SGD	0.80	Low diagnose perfor- mance scores
Sudharson et al. (2022)	Brain MRI image scans	Hybrid CNN	0.93	Low performance with a state of art approach
Sharif et al. (2020)	BRATS2017 and BRATS2018 datasets	Inception V3 pre- trained CNN model	0.92	Old datasets with low performance accuracy for diagnosis
Kibriya et al. (2022)	3064 MRI images	13-layer CNN archi- tecture	0.97	Classical neural net- works were used for classification
Yazdan et al. (2022)	3264 MRIs Scans	Multi-Scale CNN (MSCNN) architec- ture	0.91	Poor accuracy perfor- mance for multi class data
Stadlbauer et al. (2022)	1700 MRI examina- tions from advanced MRI (advMRI) and physiological MRI (phyMRI) data	Adaptive Boosting and Random Forest	0.87	Low diagnose perfor- mance scores
Fabelo et al. (2019)	26 in vivo hyper- spectral cubes from 16 different patients, among which 258,810 pixels	2D convolutional neural network	0.80	Poor accuracy perfor- mance for multiclass classification
Latif et al. (2022)	BraTS dataset	Support Vector Ma- chine (SVM)	0.96	Classical machine learning approaches were used

171 3 PROPOSED METHODOLOGY

172 This section comprehensively describes the materials and methods used to evaluate our research experi-
173 ments. We examine the MRI scans dataset and the advanced neural network approaches applied. Figure 1

illustrates our novel proposed research methodology for diagnosing brain tumors. The following steps outline the process carried out in our proposed methodology for conducting experiments.

- **Step 1:** At the outset of our research experiments, we acquired a brain tumor-related dataset of MRI scan images for evaluating results. This dataset encompasses multiple target classes, allowing for a comprehensive assessment of our findings.
- **Step 2:** Next, for the extraction of rich-level features from MRI images, we have proposed a novel neural network approach that leverages transfer learning for spatial feature extraction, ultimately creating a new feature set.
- **Step 3:** We then analyzed the dataset and identified an imbalance. To address this issue, we applied the SMOTE approach to balance the features of the dataset for multi-class classification.
- **Step 4:** The image feature data is then divided into two portions: training and testing. The split ratio employed is 80% for training and 20% for testing.
- **Step 5:** We have employed advanced machine learning and deep learning approaches in this step. Using 80% of the training data, we have implemented the applied methods.
- **Step 6:** Then, the 20% portion of the data is utilized for the evaluations and predictions of applied methods through various performance metrics in comparison.
- **Step 7:** Ultimately, the superior neural network method during experiments is employed for brain tumor diagnosis.

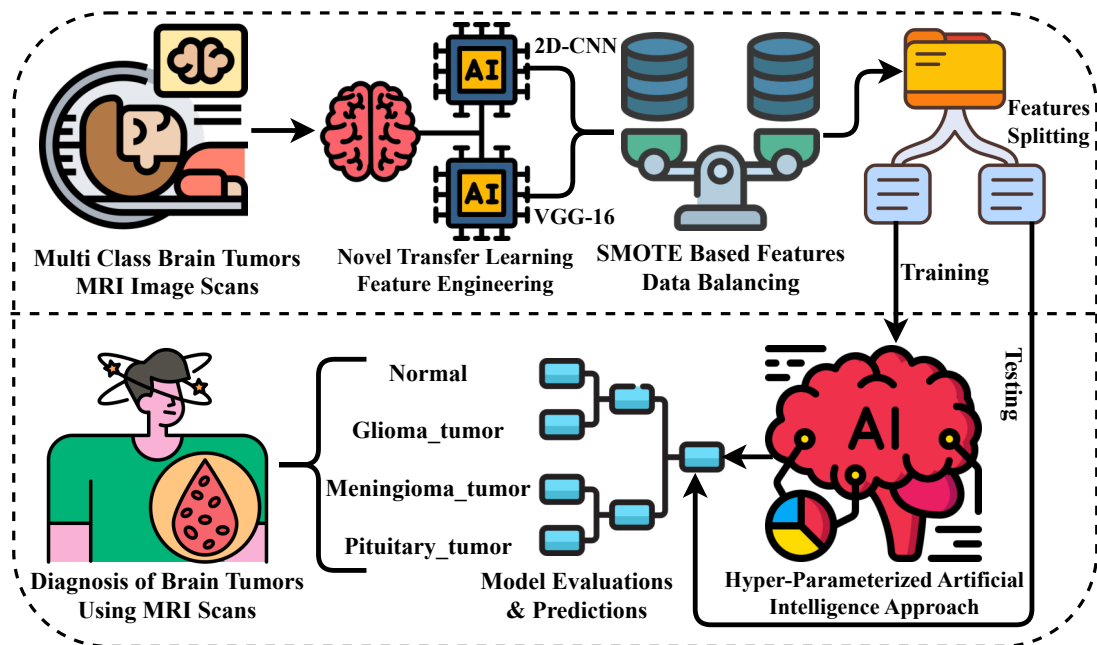

Figure 1. Workflow diagram of our proposed methodology for brain tumor diagnosis.

3.1 Multi class Brain Tumors MRI Image Data

This research used multiclass MRI scan images Hashemi (2023) related to brain tumors to conduct experiments. The dataset comprises 21,672 MRI scan images. Figure 2 illustrates the distribution of multi-class target labels. This analysis reveals that the 'Normal' target class (0) contains 3,066 samples, the 'Glioma_tumor' target class (1) contains 6,307 samples, the 'Meningioma_tumor' target class (2) contains 6,391 samples, and the 'Pituitary_tumor' target class (3) contains 5,908 samples. Additionally, we conducted a sample image analysis, as shown in Figure 3.

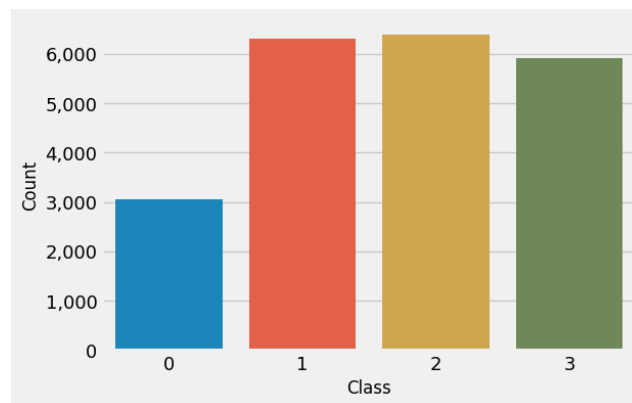

Figure 2. The target class labels distributions analysis.

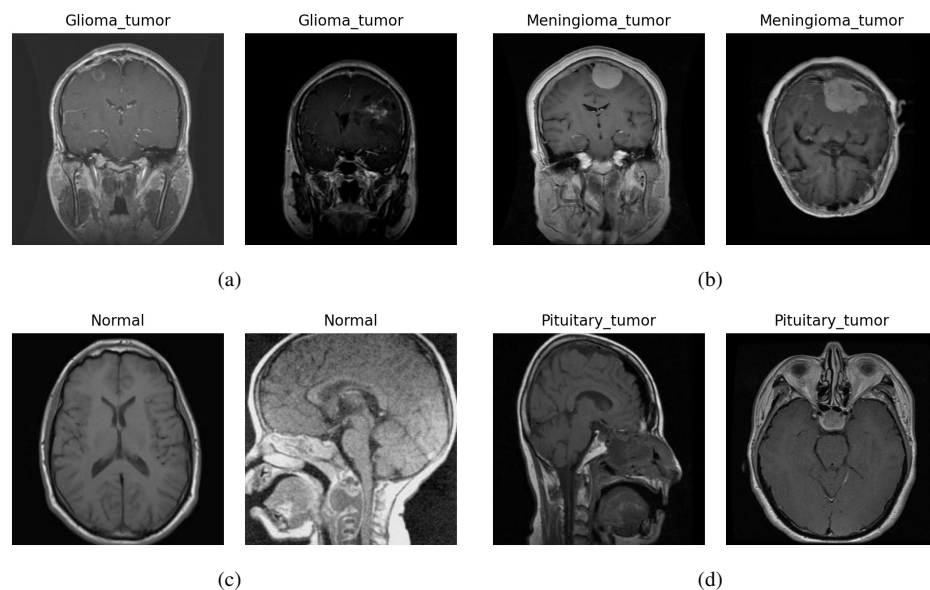

Figure 3. The sample dataset image analysis with the target class.

3.2 Novel Transfer Learning Approach

This section comprehensively describes our novel proposed CVG-Net approach for transfer feature engineering. The step-by-step architectural workflow of the proposed approach is illustrated in Figure 4. The brain tumor MRI image data is initially fed into the VGG16 approach, which extracts rich-level spatial features based on transfer learning. Similarly, the brain tumor MRI image data is input into the 2DCNN approach, which also extracts rich-level spatial features using transfer learning. The spatial features obtained from both approaches are then combined to create a new feature set. This newly generated feature set is subsequently employed in building the machine learning models applied in this study and for further results evaluations.

The algorithm 1 shows the step-by-step workflow of the proposed transfer learning feature engineering.

3.3 SMOTE based data balancing

SMOTE has emerged as a pivotal tool in addressing class imbalance issues within medical image analysis, particularly in diagnosing brain tumors using multi-class MRI image datasets Li et al. (2023b). Class imbalance, where certain classes are underrepresented relative to others, can significantly hinder the performance of machine learning models, as they tend to be biased towards the majority class. In medical imaging, this can have critical implications for patient care. SMOTE operates by generating synthetic samples in the feature space of the minority class, thereby alleviating the imbalance. When applied

216 to multi-class MRI datasets for brain tumor diagnosis, SMOTE ensures that the model is exposed to
 217 a more representative data distribution, effectively discriminating between various tumor types. This
 218 methodology has demonstrated promising results, contributing to more accurate and reliable diagnoses,
 219 paramount in clinical decision-making processes.

220 3.4 Applied Neural network methods

221 The application of artificial intelligence (AI) based machine learning, deep learning, and transfer learning
 222 methods has emerged as a transformative approach in medical imaging Rehman et al. (2023); Qadri
 223 et al. (2023); Raza et al. (2022b), particularly in diagnosing brain tumors using brain MRI scans. These
 224 advanced techniques have revolutionized the way medical professionals analyze and interpret complex
 225 neuroimaging data. Machine learning algorithms can efficiently extract intricate patterns and features from
 226 large datasets of MRI scans, enabling them to differentiate between normal brain tissue and pathological
 227 regions associated with brain tumors.

228 Deep learning, in particular, has been instrumental in automating the tumor detection, segmentation,
 229 and classification process, as it can automatically learn hierarchical representations from raw MRI data,
 230 making it highly effective in identifying subtle abnormalities. Transfer learning techniques leverage pre-

Table 2. The working mechanism description analysis of applied neural network approaches.

Method	Working Description
2D-CNN	A 2D-CNN Archana et al. (2023); Zhou et al. (2023) works by systematically scanning and analyzing small regions (kernels) of a 2D input image, such as a Brain MRI scan. These kernels extract features like edges, textures, and patterns through convolution operations. Multiple layers of convolutions and pooling are used to hierarchically learn and combine these features, enabling the CNN to detect complex patterns indicative of brain tumors, making it an effective method for automated diagnosis using MRI scans.
VGG-16	The VGG-16 neural network method Rohith et al. (2023); Shourie et al. (2023) for diagnosing brain tumors using brain MRI scans operates by utilizing a deep CNN architecture. It employs a series of convolutional layers to extract intricate features from the MRI images, gradually learning hierarchical representations of the input data. These features are then passed through fully connected layers for classification, distinguishing between tumor and non-tumor regions based on learned patterns, ultimately aiding in accurate brain tumor diagnosis.
KNC	K-Neighbors Classifier (KNC) method for diagnosing brain tumors using brain MRI scans operates by analyzing the proximity of each MRI scan to its neighboring data points in a high-dimensional feature space. KNC assigns a class label to a given MRI scan based on the majority class among its k nearest neighbors, where k is a user-defined parameter. This proximity-based approach allows KNC to effectively identify brain tumors by leveraging the collective characteristics of nearby MRI scans in the dataset, making it a valuable tool in medical image analysis Raza et al. (2023, 2022a).
LR	Logistic Regression (LR) van Ravesteijn et al. (2010) for diagnosing brain tumors using MRI scans begins by collecting a dataset of brain MRI images along with corresponding binary labels indicating the presence or absence of tumors. The LR model calculates the probability of a brain tumor being present in each MRI scan by applying a logistic function to a linear combination of image features extracted from the scans. It learns the optimal weights for these features during training. Once trained, the LR model can classify new MRI scans as tumor-positive or tumor-negative based on the probability threshold (typically 0.5), providing a valuable tool for non-invasive brain tumor diagnosis.
RF	Random Forest (RF) Dutta et al. (2023) for diagnosing brain tumors using MRI scans work by first collecting a diverse dataset of brain MRI images with corresponding tumor labels. The RF algorithm then creates multiple decision trees using random subsets of the data and features, allowing each tree to classify tumor presence or absence independently. RF combines the results from these trees through voting or averaging, resulting in a robust and accurate diagnosis of brain tumors from MRI scans.

trained models on large datasets and have shown promise in enhancing diagnostic accuracy by transferring knowledge learned from other domains or medical imaging tasks to improve the performance of brain tumor diagnosis. Integrating AI-driven methods in brain tumor diagnosis accelerates the detection process and aids healthcare providers in making more accurate and timely decisions.

In this research, we employed several advanced machine learning and deep learning-based approaches for performance evaluations. We utilized two neural network approaches, 2D-CNN and VGG16, for both classification and transferring feature mechanisms from MRI images. The machine learning models we employed include the k-neighbors classifier, logistic regression, and random forest. We have provided a detailed description of the working mechanisms of each applied neural network in Table 3.

3.5 Hyper-parameter setting

Hyperparameter tuning is a crucial aspect of optimizing neural network models in machine learning. These hyperparameters are configurations external to the model and can significantly impact its performance. In our research, we focus on systematically exploring and optimizing these hyperparameters to enhance the overall efficiency and effectiveness of neural networks. We employ a recursive process of training and evaluations to determine the best-fit hyperparameters. The selected hyperparameters for the neural

4 RESULTS AND DISCUSSIONS

The results and discussions of our study methods proposed for the diagnosis of brain tumors using brain MRI scans are analyzed in this section. We have provided a comprehensive analysis of the results obtained through the application of neural network methods. In this section, we dive into the key findings and their implications for the field of medical imaging and brain tumor diagnosis.

4.1 Experimental setup

Our proposed experimental study setup includes the use of the Google Colab platform to evaluate research results. The platform offers GPU backend support, providing 90 GB of disk space and 13 GB of RAM. We have employed the Python 3.0 programming language to build the neural network used in our research. We utilized the Sklearn, Tensorflow, and Keras modules for evaluating the results. During performance evaluations, True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN) are used as basic parameters. The performance metrics used for performance evaluation are examined as follows:

- **Accuracy:** in diagnosing brain tumors using brain MRI scans refers to measuring how effectively

the diagnostic system or method correctly identifies and classifies the presence or absence of brain tumors in the MRI images.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

• **Precision:** in diagnosing brain tumors using brain MRI scans refers to measuring how accurately the diagnostic test identifies TP cases among all the positive cases it detects.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

• **Recall:** in diagnosing brain tumors using brain MRI scans, is a fundamental performance metric that measures the ability of a diagnostic model or process to correctly identify and classify TP cases of brain tumors among all the actual cases of brain tumors present in the MRI scans.

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

• **F1:** in diagnosing brain tumors using brain MRI scans, is a measure that combines precision and recall to assess the accuracy of the classification model.

$$F1\ Score = \frac{2 \cdot Precision \cdot Recall}{Precision + Recall} \quad (4)$$

• **Runtime Computations:** is a neural network method's brain tumor diagnosis time by inputting MRI images.

• **Standard Deviations (SD):** a refers to a statistical measure of the variability of the evaluation metrics obtained from multiple folds of the dataset during the cross-validation process.

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (5)$$

4.2 Performance analysis with classical approaches

The performance analysis of the applied classical deep learning-based approaches, 2DCNN and VGG16, is conducted in this section. MRI brain scan images are fed into the 2DCNN and VGG16 methods, and the results are then evaluated.

4.2.1 Results of CNN Model

The performance results of the applied CNN model during training are illustrated in Figure 5. We conducted a time series analysis over 20 epochs of the CNN model. The evaluation is based on loss scores, accuracy, precision, and recall. The analysis reveals that the training loss is very high in the first two epochs. Subsequently, there is a notable reduction in loss, while the validation loss gradually increases. Similarly, the training accuracy starts off low in the initial two epochs, but then exhibits a steady increase. The validation accuracy scores fluctuate around 0.80. The precision and recall metrics exhibit a similar pattern to the accuracy performance scores throughout training. In conclusion, this analysis indicates that the CNN model achieved acceptable scores for brain tumor diagnosis during training. Nevertheless, there is still a need for performance enhancement.

The performance analysis of the applied CNN model for unseen testing data is described in Table 5. The analysis shows that the CNN model achieved an acceptable score of 0.76 during brain tumor diagnosis. However, the loss scores are high for the testing data. The class-wise performance scores also demonstrate moderate results. This analysis concludes that classical approaches have not proven fruitful in this case; there is a need for advanced mechanisms for performance enhancement.

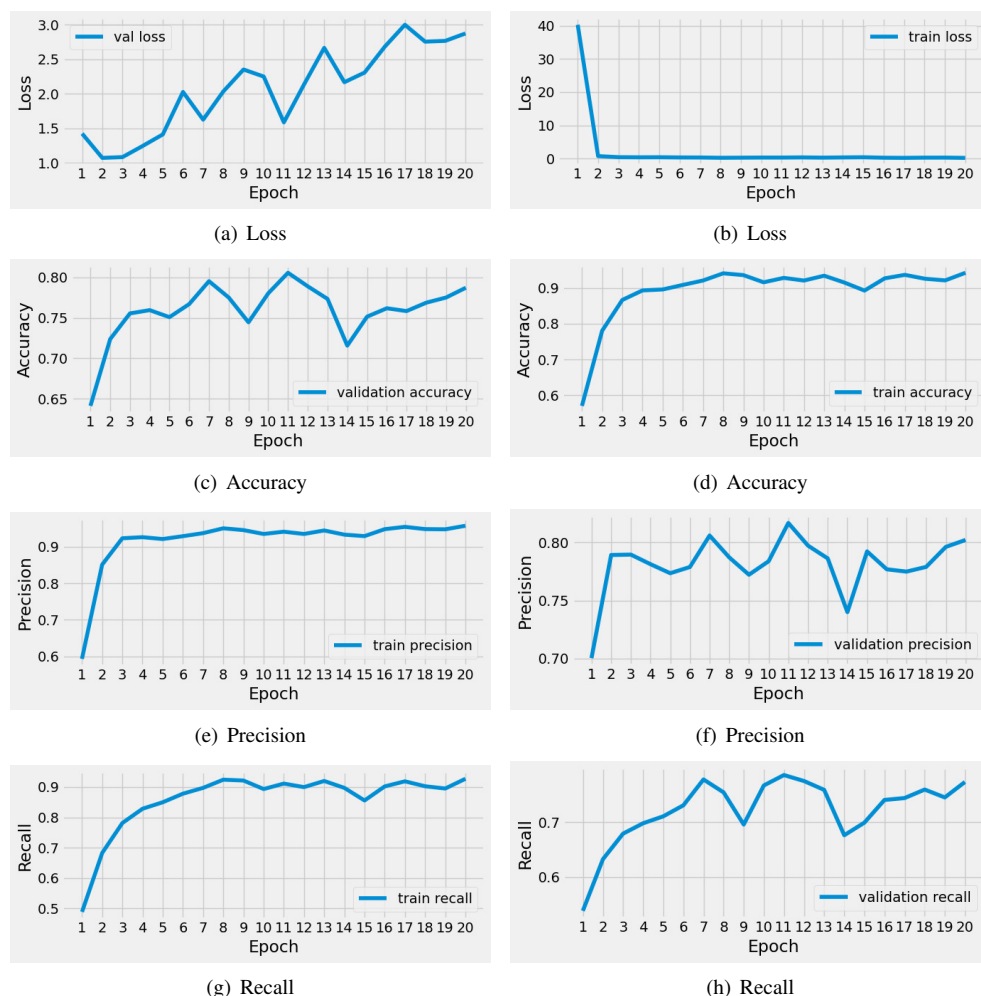

Figure 5. The time series-based results comparison of CNN model during training.

Table 5. The results analysis of applied 2D-CNN neural network.

Accuracy	Loss	Target Class	Precision	Recall	F1
0.76	3.64	Normal	0.72	0.76	0.74
		Glioma_tumor	0.70	0.68	0.69
		Meningioma_tumor	0.78	0.75	0.77
		Pituitary_tumor	0.87	0.87	0.87
		Average	0.77	0.76	0.77

4.2.2 Results of VGG16 Model

The performance results of the applied pre-trained VGG16 model during training are illustrated in Figure 6. We conducted a time series analysis over 20 epochs of the VGG16 model. The analysis reveals that the training loss is very high in the first five epochs. Subsequently, there is a notable reduction in loss, while the validation loss gradually increases. Similarly, the training accuracy starts off low in the initial two epochs, but then exhibits a steady increase. The validation accuracy scores fluctuate around 0.92. The precision and recall metrics exhibit a similar pattern to the accuracy performance scores throughout training. In conclusion, this analysis indicates that the VGG16 model achieved good scores for brain tumor diagnosis during training. Nevertheless, there is still a need for performance enhancement.

The performance analysis of the applied VGG-16 model on unseen testing data is outlined in Table 6. The analysis reveals that the VGG-16 model achieved a commendable score of 0.90 in brain tumor

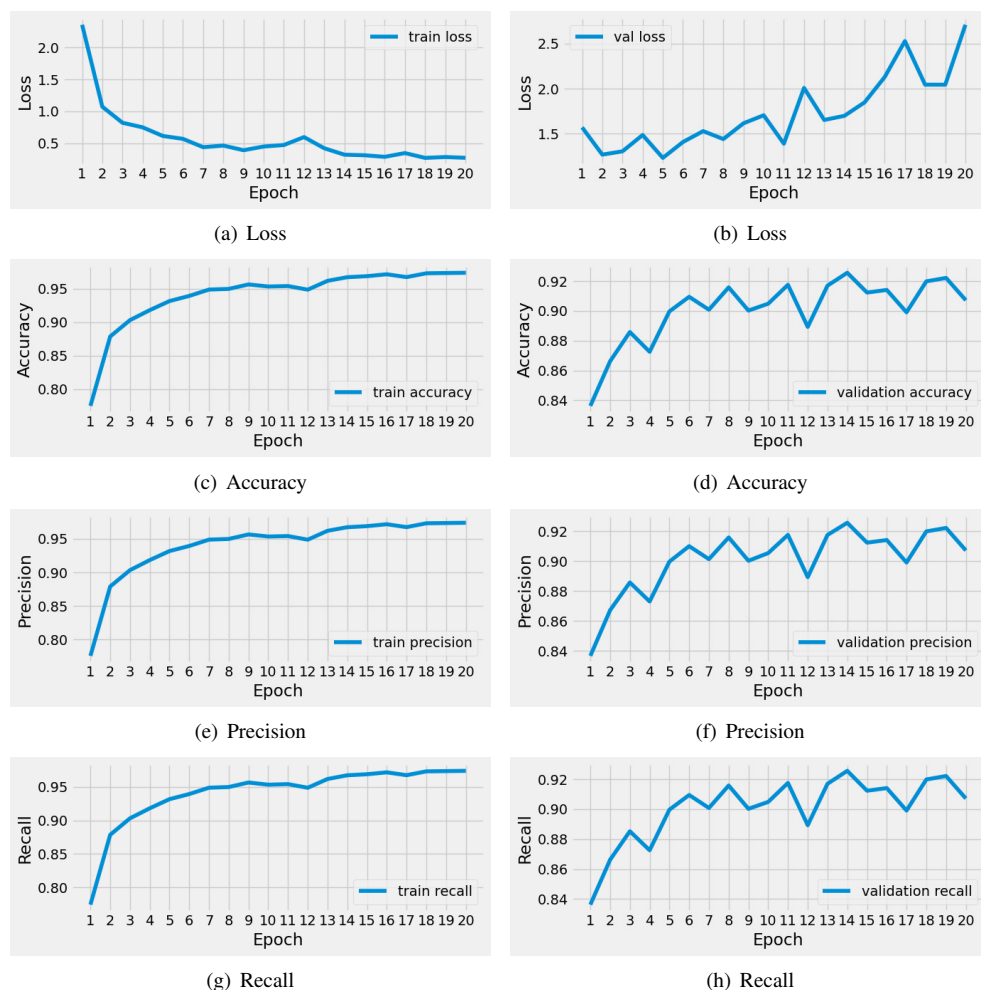

Figure 6. The time series-based results comparison of VGG16 model during training.

304 diagnosis. Nevertheless, the loss scores were notably high for the testing data. The class-wise performance
 305 scores also demonstrate positive results, with 0.91 precision and f1 scores. This analysis leads to the
 306 conclusion that classical approaches yielded a moderately satisfactory performance. However, there is a
 307 pressing need for advanced mechanisms to enhance performance.

Table 6. The results analysis of applied VGG-16 neural network.

Accuracy	Loss	Target Class	Precision	Recall	F1
0.90	2.66	Normal	0.99	0.89	0.94
		Glioma_tumor	0.91	0.85	0.88
		Meningioma_tumor	0.83	0.93	0.87
		Pituitary_tumor	0.96	0.95	0.95
		Average	0.91	0.90	0.91

308 4.3 Performance analysis with Novel approach

309 The performance analysis of the applied advanced machine learning methods with the novel proposed
 310 CVG-Net feature engineering is presented in this section. The proposed approach extracts novel transfer
 311 features by inputting MRI brain scan images into the 2DCNN and VGG16 methods, creating a hybrid
 312 feature set. The newly created features are then input into machine learning models, and the results are
 313 subsequently evaluated.

4.4 Results with unbalanced features

In this section, the novel extracted features that are unbalanced are inputted into applied machine learning methods for performance evaluations. The performance results of machine learning methods with unbalanced features are described in Table 7. The analysis demonstrates that applied machine learning models achieved high-performance scores using the novel extracted transfer features. The LR and RF achieved accuracy performance scores of 0.81 and 0.85, respectively. The applied KNC approach achieved a good score of 0.94. This analysis concludes that with unbalanced novel features, good performance is achieved. However, the performance can be further improved by applying advanced data-balancing approaches.

Table 7. The results analysis of applied neural networks with novel unbalanced features.

Method	Accuracy	Target Class	Precision	Recall	F1
LR	0.81	Normal	0.87	0.81	0.84
		Glioma_tumor	0.79	0.82	0.81
		Meningioma_tumor	0.76	0.73	0.75
		Pituitary_tumor	0.87	0.91	0.89
		Average	0.82	0.82	0.82
RF	0.85	Normal	0.95	0.85	0.90
		Glioma_tumor	0.82	0.83	0.83
		Meningioma_tumor	0.81	0.78	0.80
		Pituitary_tumor	0.87	0.95	0.91
		Average	0.87	0.85	0.86
KNC	0.94	Normal	0.94	0.93	0.94
		Glioma_tumor	0.91	0.96	0.93
		Meningioma_tumor	0.96	0.87	0.91
		Pituitary_tumor	0.95	0.98	0.96
		Average	0.94	0.94	0.94

4.5 Results with balanced features

After evaluating the performance scores with unbalanced feature data, we applied the famous data balancing Synthetic Minority Oversampling Technique (SMOTE) to the extracted feature data. The evaluation results of the applied machine learning approach with a balanced dataset are demonstrated in Table 8. The analysis reveals that balanced features help improve performance scores for the diagnosis of brain tumors. The proposed KNC method outperformed other applied methods with a high accuracy of 0.95 in comparison. This analysis concludes that SMOTE-based dataset balancing helps us improve performance scores.

The confusion matrix allows visualization of the performance of applied machine learning methods for the diagnosis of brain tumors. The overall performance validation, based on the confusion matrix, is illustrated in Figure 7. The analysis shows that the applied LR and RF have high wrong predictions for target classes 2 and 3. The minimum error rate, indicating the fewest wrong predictions, is achieved by the proposed K-Nearest Neighbors Classification (KNC) approach. This analysis validates the high-performance scores of the proposed KNC method for the diagnosis of brain tumors using MRI scans.

4.6 validating performance with k-fold mechanism

We have validated the performance of applied machine-learning approaches in this section using both unbalanced and balanced feature data. The results of k-fold cross-validations are demonstrated in Table 9. To validate accuracy performance results, we used a fold split of 10 and determined the outcomes. The analysis shows that with unbalanced features, LR and RF achieved acceptable validation accuracy scores in the range of 0.81 to 0.84. The proposed approach achieved a commendable score of 0.94. When we evaluated results with the balanced dataset, performance scores increased for each applied approach. The analysis concludes that the proposed KNC approach achieved the highest k-fold accuracy scores of 0.96 for the diagnosis of brain MRI scans.

Table 8. The results analysis of applied neural networks with novel balanced features.

Method	Accuracy	Target Class	Precision	Recall	F1
LR	0.84	Normal	0.91	0.93	0.92
		Glioma_tumor	0.82	0.79	0.80
		Meningioma_tumor	0.74	0.72	0.73
		Pituitary_tumor	0.87	0.90	0.89
		Average	0.84	0.84	0.84
RF	0.88	Normal	0.96	0.97	0.96
		Glioma_tumor	0.83	0.83	0.83
		Meningioma_tumor	0.82	0.76	0.79
		Pituitary_tumor	0.90	0.95	0.92
		Average	0.88	0.88	0.88
KNC	0.95	Normal	0.96	0.99	0.97
		Glioma_tumor	0.93	0.95	0.94
		Meningioma_tumor	0.95	0.88	0.91
		Pituitary_tumor	0.96	0.99	0.98
		Average	0.95	0.95	0.95

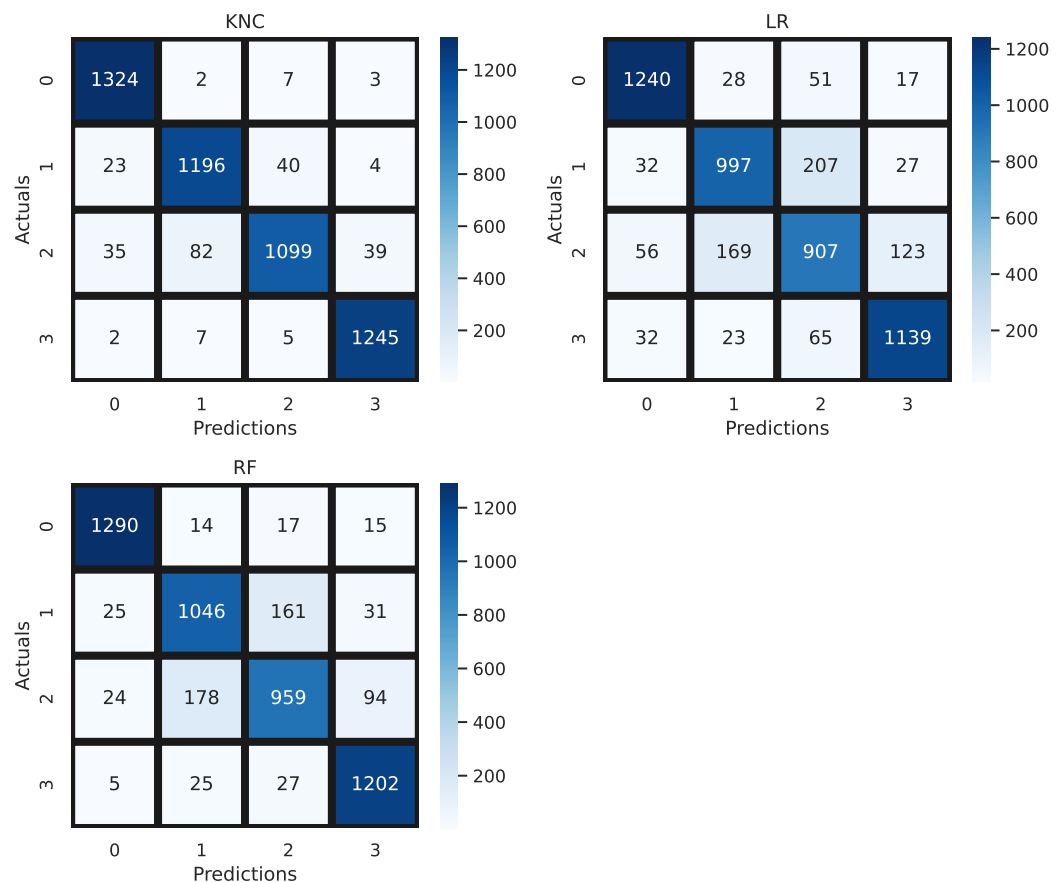

Figure 7. Confusion matrix analysis of applied neural network approaches.

4.7 Computational Complexity analysis

In this section, we present a computational complexity analysis of applied machine learning methods. The runtime computations, measured in seconds, of these applied machine learning methods, are determined during each model-building process using a newly created features dataset. The computation results are

Table 9. K-fold cross-validations results analysis of applied neural networks.

Method	Unbalanced Features		Balanced Features	
	10-fold Accuracy	SD (+/-)	10-fold Accuracy	SD (+/-)
LR	0.81	0.005	0.83	0.009
RF	0.84	0.007	0.88	0.005
KNC	0.94	0.004	0.96	0.005

350 reported in Table 10. Our analysis demonstrates that the proposed KNC method achieved the minimum
 351 runtime computations compared to other applied methods. The proposed KNC method takes only 0.0281
 352 seconds to diagnose brain tumors.

Table 10. Computational complexity analysis of applied neural networks with novel balanced features.

Method	Runtime (seconds)
LR	3.7201
RF	24.215
KNC	0.0281

353 4.8 Comparison with state-of-the-art studies

354 For a fair performance comparison, we have included state-of-the-art studies in brain tumor diagnosis
 355 in this analysis. The performance comparison of our proposed approach is illustrated in Table 11. The
 356 studies considered for performance comparison are from the years 2020, 2022, and 2023. The analysis
 357 reveals that our proposed approach outperformed state-of-the-art studies with high-performance scores of
 358 0.96 for the diagnosis of brain tumors using MRI brain scans.

Table 11. The performance comparison with state-of-the-art studies for brain tumor diagnosis.

Ref.	Year	Proposed Technique	Accuracy
Archana et al. (2023)	2023	AlexNet with SGD	0.80
Sudharson et al. (2022)	2022	Hybrid CNN	0.93
Sharif et al. (2020)	2020	Inception V3 with CNN	0.92
Yazdan et al. (2022)	2022	Multi-Scale CNN	0.91
Our	2024	CVG-Net-KNC	0.96

359 5 CONCLUSIONS AND FUTURE WORK

360 This research proposes an effective neural network approach for the timely diagnosis of brain tumors.
 361 Our experiments utilized a multi-class MRI image dataset comprising 21,672 images related to glioma
 362 tumors, meningioma tumors, and pituitary tumors. We introduced a novel neural network-based feature
 363 engineering approach called CVG-Net, which combines 2DCNN and VGG16. The proposed CVG-Net
 364 method extracts spatial features from MRI images using 2DCNN and VGG16 without human intervention.
 365 The newly created hybrid feature set is then input into machine learning models to diagnose brain tumors.
 366 We utilized four advanced machine learning models and two deep learning models based on neural
 367 networks for comparative performance evaluations. We also balanced the multi-class MRI image features
 368 data using the SMOTE approach. Extensive research experiments demonstrate that utilizing the proposed
 369 CVG-Net, the k-nearest neighbors classifier outperformed state-of-the-art studies with a k-fold accuracy
 370 performance score of 0.96. We also applied hyperparameter tuning to enhance performance for multi-class
 371 brain tumor diagnosis.

372 5.1 future work

373 In future, we intend to design a graphical user interface app for medical specialists to facilitate the effective
 374 diagnosis of brain tumors using MRI scans. Also we plan to enhance the performance by implementing

transfer learning-based advanced neural networks. The designed app will utilize the proposed approach in the backend for diagnosis.
