Comparison of hierarchies aims at identifying differences and similarities between two or more hierarchical structures. In the biological taxonomy domain, comparison is indispensable for the reconciliation of alternative versions of a taxonomic classification. Biological taxonomies are knowledge structures that may include large amounts of nodes (taxa), which are typically maintained manually. We present the results of a user study with taxonomy experts that evaluates four well-known methods for the comparison of two hierarchies, namely, edge drawing, matrix representation, animation, and agglomeration. Each of these methods is evaluated with respect to seven typical biological taxonomy curation tasks. To this end, we designed an interactive software environment through which expert taxonomists performed exercises representative of the considered tasks. We evaluated participants' effectiveness and level of satisfaction from both quantitative and qualitative perspectives. Overall quantitative results evidence that participants were less effective with agglomeration whereas they were more satisfied with edge drawing. Qualitative findings reveal a greater preference among participants for the edge drawing method. Also, from the qualitative analysis, we obtained insights that contribute to explain the differences between the methods and provide directions for future research.

14

15 Abstract

16 Comparison of hierarchies aims at identifying differences and similarities between two or more
17 hierarchical structures. In the biological taxonomy domain, comparison is indispensable for the
18 reconciliation of alternative versions of a taxonomic classification. Biological taxonomies are
19 knowledge structures that may include large amounts of nodes (taxa), which are typically
20 maintained manually. We present the results of a user study with taxonomy experts that
21 evaluates four well-known methods for the comparison of two hierarchies, namely, *edge*
22 *drawing*, *matrix representation*, *animation*, and *agglomeration*. Each of these methods is
23 evaluated with respect to seven typical biological taxonomy curation tasks. To this end, we
24 designed an interactive software environment through which expert taxonomists performed
25 exercises representative of the considered tasks. We evaluated participants' effectiveness and
26 level of satisfaction from both quantitative and qualitative perspectives. Overall quantitative
27 results evidence that participants were less effective with *agglomeration* whereas they were more
28 satisfied with *edge drawing*. Qualitative findings reveal a greater preference among participants
29 for the *edge drawing* method. In addition, from the qualitative analysis, we obtained insights that
30 contribute to explain the differences between the methods and provide directions for future
31 research.

32

33

34 Introduction

35 Visual comparison of hierarchies has been prevalent in information visualization research
36 because it is relevant for a wide range of domains such as tracking changes in software projects,
37 comparing budgets, and describing dynamics of organizational structures, among others. In this
38 work, we study the comparison of hierarchies in the domain of biological taxonomies.

39 Taxonomic information has been scattered in publications for centuries. In spite of integration
40 efforts of global initiatives in the last decades, there are numerous taxonomic databases around
41 the globe (Ball-Damerow et al., 2019). A visualization tool for the identification of differences
42 and similarities between two versions of a taxonomy would contribute to such integration efforts.

43

44 Taxonomies are hierarchies created by experts to classify living organisms. Through
45 classification, mutually resembling organisms are placed together in categories known as
46 *taxonomic ranks*, which, in turn, make up the levels of the hierarchy. The main taxonomic ranks
47 include *domain*, *kingdom*, *phylum*, *class*, *order*, *family*, *genus*, and *species*. Each node within the
48 hierarchy is referred to as a taxon, that is, a name given to a group of organisms; for
49 instance, *Vertebrates* and *Mammals* are two taxa, the former is placed at the *phylum*
50 taxonomic rank and latter at the *class* taxonomic rank. Species and sub-species are placed at the
51 lower level of the hierarchy and their scientific names are expressed with a *binomial system of*
52 *nomenclature* that uses a Latin grammatical form. The first part is the genus and the second part
53 is the *specific epithet*. For instance, the domestic cat's scientific name is *Felis catus* (formerly
54 known, for many years, as *Felix domesticus*), where the epithet name is *catus* and the genus is
55 *Felis*. Upper levels of the cat's taxonomy are: family *Felidae*, order *Carnivora*, class *Mammalia*,
56 phylum *Chordata*, and kingdom *Animalia*. For a taxon to be recorded in a taxonomy, it must
57 have been described in a publication, either as a new group or as a review of an existing group of
58 organisms. Taxonomy records may include various data; but for comparison, they are required to
59 include at least taxon name, author's name, and the year of publication. This allows users to
60 determine under which judgment the classification was devised. After almost three centuries
61 since modern taxonomy was first established by Carl Linnaeus (Linné & Gmelin, 1767), one
62 might think that most organisms on Earth have been identified and classified, and that
63 taxonomies are rather static. However, on one hand, it is estimated that only about 1.5 million
64 from approximately 11 million species of macro organisms haven been identified and described
65 (Larsen et al., 2017). On the other hand, the dynamics of taxonomic work has lead experts
66 worldwide to end up with different versions of the classifications. Taxa names represent concepts
67 whose definition depends on the authors' criteria, which eventually gives rise to conflicting
68 versions of a taxonomy. These multiple versions will require corrections and re-classifications in
69 order to come to an integrated version that can more accurately document biodiversity. That is
70 how taxonomists often face the problem of reconciling different versions of a taxonomy. For
71 such reconciliation efforts, biological taxonomists require to perform a series of curation tasks.

72

73 Sancho-Chavarría et al. (2016, 2018) characterized curation tasks that involve taxonomic
74 changes when comparing two versions T_1 and T_2 of a taxonomy. Such characterization involved
75 interviews to six experts from three different countries and followed a two-stage analysis. During
76 the first stage, the authors reviewed literature and interviewed experts in order to obtain a list of
77 preliminary tasks. In the second stage, the tasks were shared and discussed with the experts, in
78 order to obtain a final list of ten tasks. Table 1 provides a description of those derived ten tasks
79 organized into three categories, namely, *pattern identification*, *query*, and *edition*. Some of these
80 tasks are domain-independent, and are frequently mentioned in information visualization
81 research (e.g., filtering, focus, retrieving details). Other are domain-specific to biological
82 taxonomy curation work (e.g., tasks in the pattern identification category such as identify splits
83 or identify merges).

84

- 85 • *Pattern identification* tasks include the identification of *congruent*, *merged*, *split*, *renamed*,
86 *moved*, and *added/excluded* taxa, as well as the *overview* of changes and the visualization of
87 a *summary* of the resulting comparison. Congruence refers to same taxonomic concepts
88 present in both versions of a taxonomy. A split occurs when taxonomists determine that a

89 group previously considered a unit actually consists of several groups of species that should
90 be described separately. Conversely, a merge happens when taxonomists decide that several
91 independent taxa should be combined into the same group. A change of name (i.e., rename)
92 is usually due to a typo that needs to be corrected. A taxon appears moved when it has been
93 re-classified and placed in a different location within the other version of the taxonomy. An
94 addition occurs when a new taxon is added to the taxonomy, either because it is a new
95 discovery or because it had not been previously recorded in the database. Exclusions refer to
96 taxa that are contained in version T_1 but that are missing in the alternative version T_2 . It is
97 important to note that, from a taxonomic point of view, once a species is discovered, it is
98 kept in the taxonomy even if the species becomes extinct; however, in this work we consider
99 exclusions because it is important that taxonomists know when records are missing in the
100 database. The *overview changes* task refers to the possibility of globally overviewing all
101 differences between two versions of a taxonomy. The *summarize* task consists of obtaining
102 statistical information on changes.

- 103 • Curation tasks in the *Query* category enable users to obtain detailed information on taxa.
104 The *retrieve details* task lets users obtain attributes of a taxon, for instance, the year of
105 publication and the authors' names. The *focus* task refers to the action that users perform
106 when focusing on a group of organisms. Through *filter*, users may find taxa that satisfy
107 some given conditions and through *find inconsistencies*, users may recognize differences due
108 to errors or missing information (e.g., typos or undefined names).
- 109 • The *Edition* category comprises just one task that is rather ample, namely, the process
110 through which experts make changes to T_1 and/or T_2 after analyzing the results of a
111 comparison.

112
113 For this research, we considered tasks that are most relevant for the identification of changes
114 between two versions of a taxonomy, that is: 1. *Identify congruence*, 2. *Identify corrections*
115 (splits, merges, moves and renames), 3. *Identify additions/exclusions*, and 4. *Overview changes*.
116 Changes are more likely to occur at lower level taxonomic ranks, for instance, species level
117 (Vaidya, Lepage & Guralnick, 2018), therefore for this study the identification of changes will
118 be visualized only at species level.

119
120 Previous research has contributed with visual models and tools to support the comparison of
121 alternative versions of a taxonomy (Contian et al., 2016; Graham, Craig & Kennedy, 2008; Dang
122 et al., 2015). However, in practice, most taxonomists still rely on simple indented lists to carry
123 out the curation process with little computational assistance. Information visualization provides
124 visual representations that help people perform their tasks more efficiently (Munzner, 2015);
125 therefore, we believe that the identification of differences can be eased with the support of a
126 hierarchy comparison visualization system.

127
128 Graham and Kennedy (Graham & Kennedy, 2010) surveyed the comparison of hierarchies and
129 organized the visualization methods into five categories, namely, *edge drawing*, *coloring*,
130 *animation*, *matrix representation*, and *agglomeration*. The *edge drawing* method presents the
131 two hierarchies as separate structures where differences and similarities are represented by edges
132 from nodes in T_1 to the associated nodes in T_2 . The *coloring* method represents similar nodes
133 with the same color. *Animation* shows changes as smooth transitions from one hierarchy to the
134 other. In a *matrix* representation, one hierarchy is placed along the vertical axis and the other one

135 along the horizontal axis; matrix cells indicate relationships between nodes of the compared
136 hierarchies. The *agglomeration* method visually merges both hierarchies into an integrated list.

137

138 The open question that we address in this work is how well these methods support the above
139 curation tasks between two versions T_1 and T_2 of a taxonomy. From the five methods, we leave
140 out coloring as an independent condition since color can be used across all methods. We
141 designed and conducted a user study where twelve expert taxonomists evaluate those four
142 methods. We wanted participants to interact with each of the four methods in a close-to-reality
143 scenario. We developed an interactive software environment that integrates the four methods and
144 allows users to easily navigate from one method to another while doing the assessment exercises
145 (see figures 1 through 4). We wanted to capture the essence of each method and avoided the
146 introduction of features that could potentially favor any particular method. We developed the
147 software taking into consideration the importance of reaching a balanced implementation; thus,
148 the software included same functionality and a common user interface design for all methods.
149 We also carefully selected the data. Datasets contain sufficient types of changes to carry out
150 exercises for all tasks and were also selected to avoid the introduction of any bias due to the
151 potential prior knowledge of the data by the experts. Participants performed the same exercises
152 with each method; however, the target taxa were not the same, also to avoid bias from a learning
153 effect. Immediately after performing the exercises related to a task, participants were asked to
154 answer a user satisfaction questionnaire in order to evaluate each method in relation to the
155 completion of that task. We registered the participants' answers along with their interactions and
156 thinking out-loud comments. We performed a quantitative analysis on the participants' responses
157 to the exercises (i.e., whether they answered correctly or not) and also on their user satisfaction
158 assessment. Additionally, we obtained qualitative findings based on the participants' feedback
159 throughout the session. The software, the data, the questionnaire, a written guide to the tool, a
160 link to a demo video, and the analysis materials are publicly posted in Github at
161 <https://github.com/lsanchoc/MethodsTasksUserStudy>.

162

163 Our contribution with this work is twofold. On one hand, we assessed the effectiveness and level
164 of participants' satisfaction with each visualization method. Participants were likely effective
165 with three methods: *edge drawing*, *matrix*, and *animation*, and also preferred *edge drawing* over
166 the other methods. On the other hand, we obtained a set of themes that contribute to explain the
167 differences between the methods and provide valuable insights for future work on the design of
168 software tools for the comparison of biological taxonomies.

169

170 The rest of this paper is organized as follows. Section 2 presents related work. Section 3 details
171 the study design. It includes a description of the interactive software environment, the
172 participants' profile, the characteristics of the datasets, the user study protocol, and the
173 questionnaire. Section 4 describes the results of the study. In Section 5, we discuss the results
174 and present limitations and implications of the study. Finally, in Section 6, we present
175 conclusions and future work.

176

177

178 **Related Work**

179 Comparison—understood as the examination of two or more items to determine similarities and
180 differences—is a means that facilitates the process of interpreting information. Gleicher et al.
181 (2011) provide a comprehensive survey of visual comparison approaches focusing on comparing
182 complex objects. They analyze a number of publications, systems and designs, looking for
183 common themes for comparison, and propose a *general categorization of visual designs for*
184 *comparison* that consists of three general categories, namely, juxtaposition, superposition, and
185 explicit encoding. The juxtaposed designs place the objects to be compared separately, in time or
186 space. The superposed designs place the objects to be compared one over the other in an overlay
187 fashion. The explicit encoded designs show the relationships between objects explicitly and is
188 generally used when the relationships between objects are the subject of comparison. Hybrid
189 designs are also possible and usually combine two categories. More recently, a set of
190 considerations to understand comparison tasks and their challenges has been discussed (Gleicher,
191 2018), as well as comparison in the context of exploratory analysis (von Landesberger, 2018).
192 Guerra-Gómez et al. (2012) provide a classification of trees for comparison. The trees used in
193 this work are similar to Type 0 trees, which display only a label; however, nodes also contain
194 information about the author and year of publication of the species. Each node also contains the
195 list of synonyms. All these data are necessary in order to identify the types of changes.

196
197 As mentioned above, for the comparison of biological taxonomies we are considering the
198 methods surveyed by Graham and Kennedy (2010) for the comparison of two hierarchies,
199 namely, *edge drawing*, *matrix*, *animation* and *agglomeration*. Each of these methods can be
200 mapped to the mentioned *general categorization of visual designs for comparison*. So, the *edge*
201 *drawing* method comprises characteristics from both juxtaposition (hierarchies are placed
202 separately side by side) and explicit encoding (edges encode the relations between nodes); the
203 *matrix* layout corresponds to an explicit encoding design since the matrix cells can explicitly
204 indicate the relations among taxa; and *agglomeration* corresponds to a superposed design.

205
206 Previous works on hierarchy comparison match these categories. For instance, TreeJuxtaposer
207 (Munzner et al., 2003) compares phylogenetic trees by using a juxtaposed layout. It presents a
208 novel focus+context technique for guaranteed visibility and comparison is approached by
209 coloring. Holten and van Wijk (Holten & van Wijk, 2008) present a visualization method where
210 hierarchies are structured as icicle plots placed in juxtaposition. Relations are explicitly
211 represented by edges arranged through hierarchical edge bundles to reduce cluttering. The
212 Taxonomic Tree Tool (Contian et al., 2016) uses a juxtaposed layout to compare biological
213 taxonomies. It combines glyphs to explain the relations between taxa. ProvenanceMatrix (Dang
214 et al., 2015) compares two taxonomies using a matrix representation. Relations are explicitly
215 displayed through two mechanisms: glyphs and edges. Beck and Diehl (2010) compare two
216 software architectures that use a matrix. Hierarchies here are represented as icicle plots.

217
218 Examples that use animation for comparison are scarcer. Ghoniem and Fekete (2001) use
219 animation to visualize the transition between two alternative representations of the same tree laid
220 out as treemaps. Considering agglomeration-based designs, Beck et al. (2014) present a nested
221 icicle plot approach for comparing two hierarchies and Guerra-Gomez et al. (2012) contrast two
222 trees for the visualization of both node value changes as well as topological differences for the

223 comparison of budgets. Lutz et al. (2014) compared directory structures and conducted a
224 qualitative user study to identify usage strategies. Unlike the above-mentioned work, which did
225 not focus on biological taxonomies, Graham and Kennedy (2007) propose an agglomerated
226 visualization based on directed acyclic graphs for the comparison of multiple biological
227 taxonomies. They also analyzed set-based hierarchies and agglomerated graph-based
228 visualizations for the comparison of botanical taxonomies (Graham et al., 2000).

229

230 Our work differs from the above-mentioned previous studies in that, for the first time, four
231 visualization methods described in (Graham & Kennedy, 2010), are assessed for the comparison
232 of pairs of biological hierarchies with respect to typical curation tasks.

233

234

235 **Study Design**

236 The research question addressed is: “*How well does each method support carrying out biological*
237 *taxonomy curation tasks?*” This is assessed both quantitatively and qualitatively. On one hand,
238 we aim at obtaining a quantitative understanding of the participants’ effectiveness and level of
239 satisfaction. On the other hand, we also aim at obtaining qualitative insights on the capacity of
240 each method to carry out tasks for the comparison of biological taxonomies. We therefore
241 explore how users interact with the visualizations and what their judgment of each method is. We
242 opted for a within-subject design study that involves four experimental conditions, one for each
243 method (*edge drawing*, *matrix*, *animation*, and *agglomeration*). In this way, each participant
244 could test and contrast all methods. The study fits into the category “Evaluating Visual Data
245 Analysis and Reasoning (VDAR)” (Lam et al., 2012). In this approach, the goal is to assess how
246 a visualization tool supports the analytic process for a particular domain. Accordingly, in our
247 study we want to evaluate how each implemented method supports the identification of
248 similarities and differences for the curation of biological taxonomies. In order to assess each
249 method for each task individually, participants were asked to solve a task with each method, then
250 giving feedback, before moving to the next task. We favored this design over one where
251 participants would first complete all tasks with one method (before moving to the next method)
252 because we wanted to gain task-specific insights on the differences of the tested methods.

253

254 **The Software Environment**

255 We developed an interactive web-based software environment that integrates in the same
256 environment the four methods for visual comparison of biological taxonomies described in the
257 Introduction section. The software environment was designed to investigate how these four
258 methods support the taxonomy curation tasks described in Table 1. We tried to conceive a
259 balanced design within the same environment, in order not to favor any method. We also decided
260 to develop a functional system in which participants get a realistic impression. We provided
261 remote web-based access to the software because many of the participants were located in
262 different parts of the world. Figure 1 illustrates the user interface for the agglomeration method,
263 Figure 2 presents the animation method, Figure 3 presents the edge drawing method, and Figure
264 4 presents the matrix method implementation. The two taxonomies to be compared, T_1 and T_2 ,
265 are displayed as indented lists. Each method implementation is accessible by easily clicking on a
266 tab. Users can inspect the data through the provided zooming features and by vertically scrolling
267 for all methods. Additionally, horizontal scrolling is provided for *matrix*. The visualization

268 layout is of course method-dependent. For *edge drawing* and *animation*, taxonomies are placed
269 juxtaposed. T_1 is placed on the left side of the screen and T_2 on the right side. For *matrix*,
270 taxonomy T_1 is also placed on the left side but T_2 is at the top of the matrix. Finally, for
271 *agglomeration*, T_1 and T_2 are interleaved and centered horizontally.

272
273 The main menu is common to all methods, which adds uniformity to the user interface; however,
274 the implementations of the different visualizations were optimized to best reflect the intrinsic
275 characteristics of each method. The main menu is located at the top of the window and contains
276 eight toggle buttons that display the changes induced by each type of curation task that we are
277 considering, namely, *congruence*, *splits*, *merges*, *moves*, *renames*, *new*, *exclusions*, and an
278 additional *all* button. For example, when the *splits* switch is on, the visualization shows how
279 each taxon with a split in T_1 is divided into taxa contained in T_2 . The system is flexible enough to
280 allow users to turn several buttons on at the same time, in case they want to have several types of
281 changes displayed simultaneously. For *animation* (see Fig. 2) additional controls to play and stop
282 animations were added.

283
284 The color-coding scheme of the toggle buttons (i.e., tasks) is also the same across all methods
285 and defines the types of changes to be visualized. We tried to use hues that were easily
286 distinguishable to the eye in order to avoid confusion: blue for congruent taxa, pink for splits,
287 orange for merges, light green for moves, light brownish purple for renames, red for exclusions,
288 and green for added taxa. Familiar codes were also used; that is, red for exclusions and green for
289 new taxa added. The representation of relations depends on the comparison method. For
290 *agglomeration*, relations have to be inferred since data is interleaved and no explicit additional
291 marks or lines can be included easily. Hence, for this method we decided to use an augmented
292 color code in order to have a cue that would make it easier for participants to recognize to which
293 taxonomy a node belongs and to highlight the types of changes between T_1 and T_2 (i.e., the
294 relations between nodes). For this, we use the same hues but with different intensity, so the light
295 nuanced nodes in the agglomerated structure indicate that they belong to the taxonomy of origin
296 T_1 while the darker nuanced nodes indicate that they belong to the taxonomy of destination T_2 .
297 For example, a split of a taxon x in T_1 into taxa p , q , and r in T_2 would show x in light pink color
298 and p , q , and r in a darker hue of pink. A legend was added to explain this color-coding. In the
299 *agglomeration* method relations are permanent but not explicit.

300
301 In the *edge drawing* and *matrix* methods, relations are explicit and permanent. For instance, with
302 the *edge drawing* method, a split of a taxon x in T_1 into taxa p , q , and r in T_2 is shown as three
303 pink edges going horizontally from taxon x to p , q , and r in taxonomy T_2 . In the *matrix* method,
304 the same split case is shown as marked colored cells $(x; p)$, $(x; q)$, and $(x; r)$ respectively.

305
306 For *animation*, we considered two design choices: “animation by movement” and “animation by
307 emergence”. In the former, an animation consists of moving the target taxon from T_1 to its new
308 position in T_2 . In the latter, the target taxon would fade out from T_1 and would gradually appear
309 in T_2 . In either case, relations are explicit although temporary because they disappear when the
310 animation is finished. We chose the first option because the paths followed by each moving
311 taxon provides better traceability cues than the second one. Considering the split case described
312 above, the animation would show x moving towards taxonomy T_2 . On its way, x splits and
313 disappears to let p , q and r appear and keep moving until each of them reaches its definitive

314 position in T_2 . The *animation* method per se does not necessarily involve leaving an explicit trace
315 (as *edge drawing* does).

316

317 Two curation tasks do not involve relations between nodes in the alternative taxonomies,
318 namely, *identify new taxa added* and *identify excluded taxa*. Given that inclusions and exclusions
319 take place only in one of the taxonomies, the system visualizes these situations only in the
320 taxonomy in which they occurred. Thus, excluded taxa are visualized in red color in taxonomy
321 T_1 and included taxa in green color in taxonomy T_2 . Without the use of color, asking users to
322 visually infer which taxa were excluded from T_1 and which ones were included into T_2 would
323 require too much mental effort, especially when taxonomies are large.

324

325 The software included interactions that we considered crucial, such as navigating, selecting, and
326 zooming. For zooming, we took advantage of the browser's functionality and it is offered via
327 three different alternatives: a) by using the zoom feature on the browser's menu, b) using the
328 browser controls, that is, by pressing the <ctrl> key and moving the mouse scroll wheel up or
329 down, or c) pressing the key *I* on the keyboard for *zoom in* and the key *O* for *zoom out*. Functions
330 such as undo/redo, edit, and statistics were left out of the prototype since they were not crucial
331 for the study. We developed the software incrementally through several iterations until we
332 reached balanced implementations of the four methods. At the end of each iteration, computer
333 science students tested the software. Tests were also conducted involving an experienced
334 taxonomist and a PhD student in computer science.

335

336 **Participants**

337 Twelve experts were recruited from our professional network. They received no compensation.
338 Table 2 summarizes the participants' profiles. Each participant was given an identification
339 number, ranging from E1 to E12. Eight of them are botanists (three of which are also Forestry
340 engineers), two biologists (one entomologist and one ichthyologist), one ecologist, and one
341 computing engineer (with 21 years of experience in biodiversity informatics). In addition, three
342 of them reported Biodiversity Informatics as a second area of expertise. One participant holds an
343 Engineering degree, five have a Master's degree, and six have a PhD degree. Their average
344 professional experience was 28 years and their average experience in the taxonomy field was 23
345 years; this includes taxonomic classification, taxonomy nomenclature, and curation of biological
346 taxonomies. Ten participants are male and two female. Three participants worked as full time
347 university professors and the rest worked full time at herbaria, museums, or biodiversity
348 conservation initiatives. Participants came from three different countries and their expertise was
349 with different taxonomic groups of organisms.

350

351 **Datasets**

352 We carefully selected and designed the datasets, taking into account the level of familiarity
353 participants might have with the data. Although taxonomists, in general, have extensive
354 knowledge on certain groups of species, in practice, a taxonomist is only expert on a limited
355 group of organisms; therefore, not all taxonomists need an overview of large subtrees. In
356 addition, because of the large number and complexity of groups of species, their expertise is also
357 geographically focused. Thus, despite of having ten botanists in our group of experts, all of them
358 specialize in different groups of plants. In order not to favor any participant and avoid the
359 eventual bias, we did not choose groups of species that were known by any of the experts.

360 Therefore, we chose an unfamiliar taxonomy. It should not be very large since we did not want
361 to burden participants by spending too much time performing the user study. However, at the
362 same time, the dataset should be large enough to contain representative cases of all types of
363 changes. We therefore used a small-size real taxonomy and derived artificial variants from it.
364

365 We downloaded a set of 66 species of amphibians from the Catalogue of Life website
366 (<http://www.catalogueoflife.org/>) with a total of 96 nodes. We called this the *seed taxonomy*
367 from which we derived variations on the datasets (derived taxonomies) to be used for each
368 method. It was important that the data sets were different, but at the same time similar enough to
369 be comparable. Therefore, we programmed an *artificial taxonomy generator* to which we input
370 as parameters the percentage of splits, merges, movements, renames, additions, and exclusions
371 that we wanted to add to the seed taxonomy T_1 . The generator randomly selected the taxa to
372 introduce the changes and verified that only one change was introduced to each taxa to be
373 modified. In this way, we prevented data conflicts, since more than one change to a taxon could
374 generate inconsistent data. We also verified that, although questions were identical, the datasets
375 would produce different answers for each method. The number of nodes in the derived datasets
376 varied between 78 to 116 nodes. Table 3 describes the main characteristics of the four derived
377 datasets, that is, the number of nodes, of species, of splits cases, merges, moves, renames, new,
378 and excluded taxa. The goal of this setup was to ask experts to visualize changes in four pairs of
379 datasets: (T_1, T_2) , (T_1, T_3) , (T_1, T_4) , and (T_1, T_5) , with respect to *edge drawing*, *matrix*, *animation*,
380 and *agglomeration*, respectively. The derived datasets T_2 , T_3 , T_4 and T_5 are similar because they
381 are all obtained from the seed taxonomy and have roughly the same number of changes. We
382 avoided the use of the same pair of datasets across all visualization methods in order to neutralize
383 a potential bias introduced by a learning effect.
384

385 **User Study Protocol**

386 We planned the user study for a 2-hour session with each participant. During the session,
387 participants would work with the interactive software environment to perform some exercises
388 and to answer questions from a questionnaire. Seven out of the twelve experts lived overseas;
389 therefore, the session was conducted remotely via a video call for them. For the rest of
390 participants, sessions were face-to-face. For participants in remote sessions, at the beginning of
391 the session, we shared a link where the software and data were hosted. In case of the face-to-face
392 interviews, we supplied a laptop computer. In both settings, access to the software environment
393 was via web browser. We followed the same interview protocol for all participants.
394

395 A written guide and a 15-minute descriptive video of the software environment were available to
396 the participants at least two days before the session, so that they could get familiar with it.
397 Access to the software environment, datasets, and questionnaire was not provided before the
398 interview session.
399

400 A moderator was leading the session and assisted participants, while an observer was taking
401 notes. Participants did not have to write down the answers; both the moderator and the observer
402 would write the participants' answers on an answer sheet that they had previously prepared.
403 Audios of the interviews were recorded for later confirmation of answers and analysis. At the
404 beginning of the session, we checked to see if the participants had studied the guide and video
405 beforehand and if they had any questions. In case they had not done so or if they needed to

406 clarify any aspect, the moderator offered a demonstration of the software and resolved the
407 doubts. Exercises were not started until both the participant and moderator felt they were ready;
408 only then did the moderator provide the link for participants to access the interactive
409 environment. Working speed was not to be measured and participants were made aware of the
410 fact that they had no time limit to answer the questions and were able to express any inquiry,
411 doubt or suggestion at any time. Participants were also asked and reminded to think aloud while
412 solving the questions. Our goal was to get insights on how they carry out the data exploration
413 and the tasks.

414
415 We designed an instrument that consists of twelve task performing exercises, nine method
416 assessment questions and one open-ended comments section. The task performing exercises have
417 clearly correct answers and were intended to measure the participants' effectiveness. The method
418 assessment questions were intended to obtain participants' perception. The purpose of the open-
419 ended question was to obtain additional feedback on user satisfaction and suggestions for a
420 future design of an interactive visualization system. The study started with an exercise where
421 participants had to identify the most common type of change (overview task). Next, exercises
422 were targeted to identify splits, merges, renames, moves, added or excluded taxa, and ended with
423 an overview question again. Each task-performing exercise had to be answered with each
424 method. For instance, instructions such as "Use the Matrix method: Explore the visualization and
425 find into what taxa *Babina caldwelli* was split?" were followed by the same question for all
426 methods. However, the taxon to be used in each exercise (*Babina caldwelli*) was different for
427 each method.

428
429 We randomized the order in which participants used each method on each question. Participants
430 performed the exercises related to one task (for instance, identification of splits) and then were
431 asked to assess each method to perform such task. The nine method-assessment questions
432 consisted of five-level Likert scale items that assessed how good each method was to carry out
433 the task. In the course of the session, participants had access to a copy of the questions and
434 instructions, especially because taxa names were in Latin, and we wanted to avoid any
435 confusion.

436

437 **Analysis**

438 For the analysis of the results, we organized the participants' responses into a spreadsheet. We
439 gathered three types of data: a) the effectiveness data, i.e., whether the participants answered
440 each question correctly or incorrectly, b) the user satisfaction data, i.e., the Likert-scale ratings
441 that participants gave to each method after accomplishing each task, and c) the qualitative data,
442 i.e., the thinking-aloud comments and the suggestions that participants provided during the
443 session. Quantitative analysis was performed on data of types a) and b) by using a statistical
444 package. We used non-parametric statistics with $\alpha=0.05$ and compared medians to determine
445 that differences are not due to chance. For the analysis of effectiveness, we used the Cochran's Q
446 test, which can be used when you have a group of people performing a series of tasks where the
447 outcome is dichotomic (e.g. success or failure). For the analysis of participants' satisfaction, we
448 used the Friedman test, which is appropriate for within-subjects designs that have three or more
449 conditions, and particularly it can be used for the analysis of ordinal data, such as the Likert-
450 scale responses (MacKenzie, 2013). When necessary, both tests were followed by pairwise
451 comparison using Dunn's test with Bonferroni correction.

452

453 For the qualitative analysis, we applied the following procedure. The responses were first placed
454 in the same order in which the questions were presented to the participants, and, then, they were
455 sorted by method. Two columns were designated for each participant, one to record their
456 comments and suggestions (e.g., E1) and another one to afterwards register the codes generated
457 during the qualitative analysis (e.g., E1-codes). Secondly, we listened to the audio recordings
458 checking for additional feedback from the participants, which we added to the spreadsheet.
459 Thirdly, we conducted a qualitative analysis: the first author made several coding passes using
460 *open coding* (Charmaz, 2006) to obtain a first coding version that was then shared with the other
461 authors. We coded participants' interactions and feedback. Repeated or related topics were
462 grouped together, revised and re-grouped through several refinement cycles until we reached an
463 agreement with twelve categories to finally conclude with four meaningful themes. During the
464 process, we also organized the positive and negative comments, as well as the participants'
465 suggestions for improving the methods.

466

467 Results

468

469 The study took 2:15 hours on average per participant. We first present quantitative results on
470 participants' effectiveness and satisfaction, and then findings from the qualitative analysis.

471

472 Effectiveness

473 The results of the participants' effectiveness on the task-performing exercises are summarized in
474 Table 4. Overall results indicate that participants obtained more correct answers with *matrix*
475 (94%), then with *edge drawing* (88%), followed by *animation* (87%) and then with
476 *agglomeration* (73%). We tested for statistical significance by using Cochran's Q test for N=12
477 and DF=3. We did not find significant differences on participants' responses between pairs of
478 methods (*matrix, edge*), (*matrix, animation*), and (*edge, animation*). However, we did find
479 differences ($\chi^2=40.480$, p-value = 0.05) between agglomeration (73%) and the other methods,
480 meaning that participants were less effective with the agglomeration method.

481

482 We also did a quantitative analysis on responses to each exercise. We did not find significant
483 differences among participants' responses when identifying: a) into which taxa a taxon was split
484 (exercise 2), b) whether species were merged and how (exercises 4 and 5), c) whether species
485 were renamed (exercises 6 and 7), d) whether any species were added to a version of the
486 taxonomy (exercise 9), and e) whether any species were excluded (exercise 10). We found
487 significant differences in participants' responses in identifying: a) an overview of changes
488 (exercises 1 and 12), b) which species were most divided (exercise 3), c) moved taxa (exercise
489 8), and d) all changes on a taxon (exercise 11). For these cases, a post hoc pairwise comparison
490 was performed in order to determine where the differences occurred. Resulting less-effective
491 methods are highlighted in orange color in Table 4:

- 492 • Exercise 1. Overview of changes. We found differences ($\chi^2=25.500$, p-value < 0.05) between
493 the following pairs of methods: (*animation, edge drawing*), (*matrix, edge drawing*) and
494 (*agglomeration, edge drawing*). This indicates that the effectiveness with *edge drawing* (8%)
495 was lower with respect to *agglomeration* (75%), *animation* (92%) and *matrix* (92%).
- 496 • Exercise 3. Identification of splits. We found differences ($\chi^2=17.571$, p-value < 0.05) between
497 pairs of methods (*edge drawing, agglomeration*) and (*matrix, agglomeration*). These results

498 indicate that the effectiveness with *agglomeration* was different with respect to the other
499 methods. Participants were less effective with *agglomeration* (33%) and more effective with
500 *edge drawing* (100%) and *matrix* (92%).

- 501 • Exercise 8. Identification of moved taxa. We found differences ($\chi^2=21.000$, p-value < 0.05)
502 between pairs of methods (*animation, agglomeration*), (*edge drawing, agglomeration*), and
503 (*matrix, agglomeration*). This indicates that participants were less effective with
504 *agglomeration* (42%) whereas they were more effective with the other methods (100%).
- 505 • Exercise 11. Focus on a taxon. We found differences ($\chi^2=9.692$, p-value < 0.05) between the
506 pair of methods (*agglomeration, matrix*). This indicates that participants were less effective
507 with *agglomeration* (50%) and more effective with *matrix* (100%).
- 508 • Exercise 12. Overview of changes. We found differences ($\chi^2=10.714$, p-value < 0.05)
509 between pairs of methods (*animation, agglomeration*), (*edge drawing, agglomeration*), and
510 (*matrix, agglomeration*). This indicates that participants were less effective with
511 *agglomeration* (17%) than with *animation* (58%), *edge drawing* (58%), and *matrix* (58%).

512

513 Satisfaction Level

514 Right after carrying out the task-performing exercises for each task, participants answered a
515 Likert-scale questionnaire to assess the methods. The questions had the following structure:
516 “How good do you think each method is in order to perform task t? For each method provide a
517 rating between 1 and 5, where 1 stands for ‘poor’, 2 for ‘fair’, 3 for ‘good’, 4 for ‘very good’,
518 and 5 for ‘excellent’”. We performed a statistical analysis on the participants’ ratings using the
519 Friedman test. Table 5 summarizes the results for N=12 and DF=3. We did not find any
520 difference in participants’ responses to accomplish the task for the identification of excluded
521 species (question 10e). Neither we found differences regarding the identification of added
522 species (question 9e) after running the post pairwise comparison. On the contrary, we found
523 differences in participants’ responses to carry out tasks for the identification of the most common
524 type of change (1e), splits (3e), merges (5e), renaming (7e), moves (8e), changes to a taxon (12e)
525 and the general methods assessment question (13). The post hoc pairwise comparison gave the
526 following results (in Table 5, higher satisfaction level is shown in green and less satisfaction
527 level is highlighted in orange):

528

- 529 • Question 1e-overview ($\chi^2=12.588$, p-value = 0.05). We found differences between pairs of
530 methods (*animation, edge drawing*). Participants gave a better rating to the *edge drawing*
531 method (median = 3.29 ~ ‘good/very good’) than *animation* (median = 1.79 ~ ‘fair’).
- 532 • Question 3e-splits ($\chi^2=33.055$, p-value = 0.05). We found differences between pairs of
533 methods (*agglomeration, matrix*) (*agglomeration, edge drawing*) (*animation, matrix*), and
534 (*animation, edge drawing*). There was no difference between *agglomeration* and *animation*,
535 and neither *matrix* and *edge drawing*. Participants ratings for *agglomeration* (median = 1.50
536 ~ ‘poor/fair’) and *animation* (median = 1.50 ~ ‘poor/fair’) were the lowest while for *matrix*
537 (median = 3.21 ~ ‘good’) and *edge drawing* (median = 3.79 ~ ‘good/very good’) were the
538 highest ones.
- 539 • Question 5e-merges ($\chi^2=20.050$, p-value = 0.05). We found differences between pairs of
540 methods (*animation, edge drawing*) and (*agglomeration, edge drawing*). Participants
541 assessed the *edge drawing* method with the highest rating (median = 3.71 ~ ‘good/very
542 good’) compared to *agglomeration* (median = 2.0 ~ ‘fair’) and *animation* (median = 1.71 ~
543 ‘poor/fair’).

- 544 • Question 7e-renames ($\chi^2=21.559$, p-value < 0.05). We found differences between pairs of
545 methods (*animation*, *edge drawing*) and (*agglomeration*, *edge drawing*). Participants
546 assessed the *edge drawing* method with the highest rating (median = 3.67 ~ ‘good/very
547 good’) than *agglomeration* (median = 2.13 ~ ‘fair’) and *animation* (median = 1.50 ~
548 ‘poor/fair’).
- 549 • Question 8e-moves ($\chi^2=24.295$, p-value = 0.05). We found differences between pairs of
550 methods (*agglomeration*, *edge drawing*) and (*animation*, *edge drawing*). Participants
551 assessed the *edge drawing* method with the highest rating (median = 3.83 ~ ‘very good’) than
552 *agglomeration* (median = 1.54 ~ ‘poor/fair’) and *animation* (median = 1.88 ~ ‘poor/fair’).
- 553 • Question 12e-focus ($\chi^2=16.057$, p-value = 0.05). We found differences between pairs of
554 methods (*animation*, *edge drawing*) and (*agglomeration*, *edge drawing*). Participants
555 assessed the *edge drawing* method with the highest rating (median = 3.46 ~ ‘good/very
556 good’) than *agglomeration* (median = 1.88 ~ ‘fair’) and *animation* (median = 1.79 ~ ‘fair’).
- 557 • Question 13-general assessment of all methods. ($\chi^2=16.057$, p-value = 0.05). We found
558 differences between pairs of methods (*animation*, *edge drawing*) and (*agglomeration*, *edge
559 drawing*). Participants assessed the *edge drawing* method with the highest rating (median =
560 4.97 ~ ‘excellent’) than *agglomeration* (median = 2.97 ~ ‘good’) and *animation* (median =
561 2.84 ~ ‘good’).

562

563 It is important to notice that response for question 13 summarizes the participants’ level of
564 satisfaction.

565

566 Findings from Qualitative Analysis

567 Regarding *edge drawing*, all participants referred to this method throughout all exercises with
568 expressions such as: “easy”, “very direct”, “I can easily relate taxa”, “it is very fast”, “I do not
569 have to think too much”, and “you can see ... at a glance”. One participant (E6) said that it was
570 the best because “you can clearly see the origin and the destination”. Another participant (E7)
571 considered that *edge drawing* “is familiar, it is similar to an ‘associate’ type of exercise”.

572

573 Participants’ feedback on *matrix* highlighted this method as good for the visualization of general
574 overviews and the identification of patterns, eight participants mentioned it (E2, E3, E7, E8, E9,
575 E10, E11, and E12). Five participants (E6, E7, E10, E11 and E12) mentioned that *matrix* was the
576 fastest one. Another participant (E2) recognized that “it is easy to see in a row the changes to a
577 taxon”. Three participants (E10, E11 E12) considered that the required vertical and horizontal
578 scrolling add complexity and two other participants (E2 and E10) mentioned that scaling could
579 be a problem. One participant (E1) complained that he had to use his fingers on the screen to
580 follow the relations in the two dimensions. Eleven participants complained about the vertical
581 name implementation in the top hierarchy (all except E2), and two participants (E1 and E10)
582 found navigation difficult because parts of the hierarchies were off the screen.

583

584 Regarding *animation*, two participants (E1 and E8) rated it positively indicating that it was
585 “dynamic”, and therefore “fun”. However, eight out of the twelve participants described this
586 method in negative terms such as “difficult”, “ineffective”, “hard to follow”, “complicated”, “not
587 intuitive”, and “waiting until the end of the animation is a waste of time”. Five participants
588 considered that the *animation* was not necessary. Participants emphasized that changes between
589 the two taxonomies were very difficult to follow because they could very soon forget what

590 happened, especially if taxonomies were large. Five participants indicated that, while taxa were
591 moving, it was easy to lose track of the relation between origin and destination because the taxa
592 were moving. Most participants speeded up the animation, giving the impression that they
593 wanted it to get to an end quickly, but some had to execute it several times before being able to
594 solve the exercise.

595

596 Participants indicated that it was very difficult to carry out the tasks with the *agglomeration*
597 method, except for the identification of excluded taxa. Eight participants (E2, E5, E7, E8, E9;
598 E10, E11, E12) referred to *agglomeration* as very good when looking for specific taxa or to
599 focusing on a small part of the taxonomy. However, all participants also described it in negative
600 terms, such as “difficult”, “very complicated”, “requires too much effort”, “not evident”,
601 “confusing”, and “very difficult to know origin and destination”. Participants complained that
602 this method involved many variables that were difficult to remember (that is, many color hues)
603 and that it required considerable effort to recognize differences. However, two participants
604 thought that the *agglomeration* view could be complementary to *edge drawing*, and that it could
605 work well for small taxonomic groups.

606

607 We coded and organized the participants’ feedback until we reached themes that we considered
608 meaningful. Our observations show four specific issues that are relevant when performing tasks
609 for the curation of biological taxonomies:

610

- 611 • **Explicit representation of changes.** Changes are visualized through relations among taxa. Nine
612 out of twelve participants clearly indicated that being able to identify the origin and
613 destination of relations was very important to recognize changes when comparing biological
614 taxonomies. Participants’ suggestions such as; “add edges to animation”, “add edges to
615 matrix”, or “add numbers to each change in the agglomeration method” are indications that
616 they would prefer to see relations explicitly and, therefore, prefer methods that explicitly
617 represent the changes.
- 618 • **Efficiency.** Participants often commented about speed and time needed to solve the exercises.
619 Across exercises, they referred to the importance of understanding what is going on at a
620 glance. They expressed feeling frustrated when having to wait for the animation to end. They
621 speeded up the animation when they felt that solving the exercise was taking too much time.
622 Participants considered that having to scroll horizontally and relate rows and columns of the
623 matrix or having to interpret different colors as in *agglomeration* were steps that consumed
624 time.
- 625 • **Multiple views.** Several participants commented that the methods could be complementary;
626 for instance, that the *edge drawing* and the *matrix* methods could be used to visualize all
627 cases at once whereas the *animation* and the *agglomeration* methods could be useful when
628 analyzing smaller groups of species. They explained that, by combining several methods, the
629 advantages of one method could overcome the disadvantages of another one. On the other
630 hand, the experts also emphasized the convenience of having both overview and detailed
631 views; the first one to obtain a general understanding of changes and the second one to obtain
632 detailed information on a focused part of the taxonomies.
- 633 • **Visual and numerical summaries.** When asked for number of taxa that match a certain
634 condition, participants expressed their frustration because they had to count manually and
635 suggested to add statistics to the software environment. Although obtaining statistical

636 information is one of the tasks for the curation of biological taxonomies, we decided to leave
637 it out of this study on purpose in order to force participants focus on the visualizations. The
638 intention of quantity-related questions was to see if participants were able to visually identify
639 magnitude of changes (for instance, matrix resulted good). We obtained confirmation on the
640 importance of providing numerical understanding of changes.

641

642 **Suggested Improvements**

643 The methods that received most suggestions for improvement were the ones that had the lowest
644 participants' effectiveness and preference. Suggestions for agglomeration focused on
645 mechanisms that would make the relations explicit somehow and allow them to be recognized
646 quickly. For instance: a) add numbers instead of different color hues to indicate taxa of the origin
647 and taxa of the destination, b) use a different color hue for each change (not only for each type of
648 change), c) instead of using several color hues, consider glyphs or some other visual cues, d)
649 color the background of the text instead of the text, e) visually separate the taxonomies on user's
650 demand, f) separate the legend so that hues associated to origin are placed on the left side and the
651 hues associated to the destination are placed on the right side of the screen. For animation
652 participants provided suggestions such as: a) add a time slider and a rewind button, b) identify
653 each change with a number, c) add traces as in edge drawing, d) identify each specific change
654 with a different color, e) maybe consider the use of animation for comparing a small part of the
655 taxonomies. For matrix, participants also made suggestions to improve the visualization of
656 relations; for instance, a) add a feature to freeze rows or columns in place and ease the
657 visualization of relations when vertical or horizontal scrolling is needed, b) add horizontal and
658 vertical guiding lines to ease following the relations, c) add a colored rectangle around the
659 excluded or added taxa in order to highlight these changes, d) add edges in order to make the
660 relations more explicit, e) consider the matrix method as a way to feed a database with the
661 relations between the two taxonomies. Suggestions for edge drawing included: a) use more
662 intense color hues and b) provide features that ease the comparison between taxa of higher
663 taxonomic ranks (for instance, at the family level). Three participants (E3, E5, E6) mentioned on
664 several occasions that the identification of relations was easier when the involved taxa were
665 closer together, within the same view. They expressed this thought as they were solving matrix
666 and agglomeration exercises. On the other hand, four participants (E3, E6, E10, E12) mentioned
667 that vertical scrolling was fine in edge drawing, since "it is very familiar". Feedback obtained
668 from the open-ended comments section of the questionnaire also included suggestions for
669 enhancements to the implementation of the methods. Regarding the representation of hierarchies,
670 participants' suggestions included the elimination of lines that indicate hierarchical structure and
671 to use only indentation as a visual cue to recognize hierarchy (some participants believed that the
672 visualization could look cleaner). They also mentioned that the visual clutter caused by long
673 names might be overcome by using abbreviations when possible (for instance, for the genus part
674 of the species names).

675

676 **Discussion**

677

678 The research question we investigated was how well each of the four methods of hierarchy
679 comparison supports the tasks of contrasting two versions of a taxonomy. The quantitative and
680 qualitative results revealed differences among the methods. The difference in effectiveness
681 occurred only with respect to agglomeration, as the participants were the least effective with this

682 method. One likely explanation is that in all methods, the changes between the two taxonomies
683 were consistently represented throughout predetermined colors for each type of change, but in
684 agglomeration each change was represented by two tonalities of the predetermined color, one to
685 indicate the taxon of origin and the other to indicate the taxon of destination. This might have
686 added complexity that affected the participants' effectiveness with this method. Overall,
687 participants were very effective with the other three methods, which might be because the
688 participants could take as much time as they considered necessary to solve the exercises. The
689 number of correct answers with animation and with edge drawing was quite similar (125 and 126
690 respectively). In spite of this similarity in the participants' accuracy, and that both methods used
691 juxtaposed layouts, the user satisfaction results indicate greater participants' preference for edge
692 drawing. Comparing the amount of correct answers, participants showed similar performance in
693 many exercises with edge drawing and matrix. The difference between these two methods comes
694 mainly from the responses to the overview exercise where they had to identify "1. Which is the
695 most common type of change?" where only one participant answered correctly with edge
696 drawing and 11 participants with matrix. This might indicate that matrix works well to get a
697 general overview of changes. This is reflected also in the participants' feedback when they
698 highlighted that this method was good for pattern recognition.

699
700 The effectiveness on recognizing new taxa or excluded taxa was similar with all methods. This is
701 explained by the fact that both new and excluded species are visualized only in one of the
702 taxonomies, and require no relations between the involved taxonomies.

703
704 In another respect, we noticed that participants were more effective at identifying changes at the
705 lowest level of the taxonomy (i.e., species level) than when trying to recognize changes at upper
706 levels (such as at the genus level, exercise 12). This might suggest the convenience of having
707 summary overviews on changes at higher-level taxa.

708
709 Both the quantitative and the qualitative analysis coincide that the agglomeration method ranked
710 last. In spite that the results on effectiveness did not show clear differences among animation,
711 edge drawing and matrix, both the participants' feedback on satisfaction and the qualitative
712 findings suggest edge drawing in the first place.

713 714 **Threats to Validity**

715 Various factors can limit the validity of the results of visualization user studies, including the
716 number of participants, the choice of the datasets, the design of the study, and the data analysis.

717
718 The study included twelve expert users. A small number of participants can affect the quality of
719 results, especially with respect to quantitative results. However, with respect to qualitative
720 findings, the number was sufficient: After completing a first set of nine interviews, we recorded
721 the data on a spreadsheet and did a preliminary processing. Afterwards, when we finished all
722 twelve interviews, we noticed that the qualitative results repeated (that is, with 33% more
723 participants than in the preliminary processing). Such consistency is an indication of
724 dependability regarding the qualitative results.

725
726 In spite of the tasks randomization, given the small number of participants, bias might have been
727 introduced by the learning effects.

728

729 A restriction of the study is the small size of the datasets, which contained between 78 and 116
730 nodes. As the data were unknown to all participants, the datasets had to be restricted to a small
731 size in order to carry out the study in reasonable time. Still, the datasets contained all types of
732 required changes to perform the tasks. In the case of the dataset for matrix, it turned out a little
733 smaller than the other ones, but large enough to allow users to experience both horizontal and
734 vertical scrolling, so we considered it was fine for the study; however, the difference in size
735 compared to the other datasets might have added some bias to the study. For visualizing larger
736 excerpts or whole taxonomies, other visualizations might be necessary, and our results may not
737 generalize to this. Also, the binding of datasets to methods could have introduced a slight
738 confounding factor but seemed an acceptable risk, which we took to simplify the evaluation
739 logistics.

740

741 Although the transferability of results is limited by a) the specific domain application, b) the
742 tasks studied, and c) the data sets, the comparison of hierarchical structures is independent of the
743 application domain; thus, some features of the study might contribute to other contexts where
744 users need to identify divided, joined, moved or renamed nodes between two hierarchies.
745 The within-subject design is applied in studies with a small number of participants. All
746 participants interacted with every method. In this way, we expected to reduce biases associated
747 with individual differences. However, the within-subject design may bias participants because of
748 the carry over effect; that is, once participants perform a task with one method, they may expect
749 certain conditions to happen in the next method to evaluate. We tried to counterbalance bias from
750 the learning and tiring effects by asking participants to interact with the methods in a randomly
751 established order. In addition, although the questions were identical, the data sets would produce
752 different answers for each method in order to prevent the learning effect.

753

754 A bias may be introduced by the design of the study or the design of the interactive software
755 environment. We tried to implement the essence of the methods as well as to keep a standard
756 user interface for all visualizations (same main menu and color codes throughout all methods),
757 but limitations may come from the design choices and implementation decisions. For instance,
758 zooming and scrolling features were limited and not designed for very large amounts of data;
759 also, participants were unsatisfied regarding the vertical text orientation of the matrix
760 implementation. Applying coloring was more difficult in the agglomeration approach because, in
761 this method, color is also required to indicate the different versions of the taxonomy. We decided
762 for a mixed brightness and color encoding as a tradeoff, which seemed introducing a smaller
763 bias, instead of avoiding the use of color for encoding types of changes or introducing an
764 inconsistent use of color across the methods.

765

766 We aimed to objectively examine the collected data. For the quantitative part of the study, we
767 used statistical tests to analyze if the differences between the medians were significant. For the
768 qualitative part of the study we carefully organized the data and coded the participants' feedback
769 and interactions through several refinement cycles. By counting and grouping similar feedback
770 from participants, we were able to define the codes and themes. Nonetheless, the interpretation
771 of the data may be subject to the perspective of the researchers.

772

773 **Implications**

774 The participants performed well with edge drawing and consider it, in general, the best method;
775 despite they did not have the best performance with it. For overview tasks, participants showed
776 similar effectiveness with matrix and animation, however they preferred matrix.

777

778 Results indicate that identifying explicitly the origin and destination of taxa is very relevant for a
779 more efficient identification of changes; edge drawing and matrix methods seem to have
780 facilitated it. The participants' need to determine origin and destination may explain that edge
781 drawing outperformed animation in both effectiveness and user satisfaction. Both methods
782 present the taxonomies in a juxtaposed layout, however, relations are not explicit in animation.
783 Some participants considered that animation could be useful to focus on changes in small
784 taxonomic groups, which reaffirms the scope of animations, as indicated by Graham and
785 Kennedy [11].

786

787 During the sessions, we noticed that sometimes taxonomists wanted to see the big picture and
788 then focus on a smaller group of organisms of their interest. Also, sometimes they wanted to go
789 directly to the group they want to inspect. Thus, future research should consider easily toggling
790 between overview and detailed views as well as search and filtering functions. Text (that is, taxa
791 names) is crucial when comparing taxonomies. Visual cues such as color, size, shapes or glyphs
792 are not enough to recognize the differences and similarities. Text must be legible. The users
793 would have to read names, which would need to be accommodated efficiently avoiding
794 cluttering. Unlike other studies, we were not assessing how participants use the tool [18], neither
795 we were measuring the prototype efficiency for comparing hierarchies [12]. Instead, our
796 contribution lays in the assessment of the four visualization methods for the comparison of pairs
797 of biological hierarchies with respect to curation tasks.

798

799 A final remark about methods and tools for the comparison of biological taxonomies is that the
800 methods we evaluate in this work are those that have been mainly discussed in the scientific
801 literature; however, their implementation in tools is limited. The Taxonomic Tree Tool (Lin et
802 al.) is, as far as we know, one of the few tools available online that allows us to explore
803 relationships (such as ancestor-descendant relationships) when comparing two biological
804 taxonomies. In a post-study contact with some participants, we asked about the software they use
805 for taxonomy comparison. We obtained five responses and only one indicated to occasionally
806 use the Taxonomic Name Resolution Service (<http://tnrs.iplantcollaborative.org>) to compare a
807 list of plant names with an authoritative database of published names. We do not know the
808 precise reasons why the methods are not in widespread use, but some possibilities could be that
809 the developments only reached prototype versions and are not available online, that the
810 visualizations could be too complex, or the difficulty that comes with the lack of standardization
811 of data in different communities.

812

813

814 **Conclusions and Future Work**

815

816 This study contributes insights on the capacity of four visualization methods for hierarchy
817 comparison in typical biological taxonomy curation tasks. Twelve expert taxonomists took part

818 in a study and provided feedback. We performed quantitative as well as qualitative analysis. The
819 results clearly show differences among the methods, on both users' effectiveness and
820 satisfaction: the edge drawing method was preferred over other methods.

821
822 In this study, the data sets were selected to avoid bias, all participants used the same datasets, and
823 participants were able answer the questions in reasonable time. However, it will be interesting to
824 design a similar study with larger datasets. Another approach would be to design a study in
825 which the data would be specific and familiar to each participant.

826
827 Enhancements such as providing multiple views, adding visual cues at inner taxonomic rank
828 levels, and avoiding overloading caused by long names and hierarchical structure lines, are
829 insights for future research. Functions for searching, statistics and queries to retrieve the
830 information of a taxon will be considered in a future design of a visualization environment. We
831 also plan to further research on visual summary views to facilitate the comparison at different
832 taxonomic rank levels. Finally, it will be important to make biological taxonomy comparison
833 visualization tools available for use. This implies overcoming challenges such as promoting the
834 standardization of data to facilitate data sharing and comparison.

835
836

837 **Acknowledgements**

838 The authors would like to thank all expert taxonomists who collaborated with this research,
839 dedicated the time to participate and provided very valuable feedback. We would also like to
840 thank Eros Hernández-Romero and Ronald Andrés Bolaños-Rodríguez for their collaboration
841 during the software development and the interview sessions, and Shivam Agarwal for his
842 collaboration as test participant.

Table 1 (on next page)

Biological taxonomy curation tasks.

| Category | Task |
|------------------------|---|
| Pattern Identification | 1. <i>Identify congruence</i> : Identify same taxonomic concepts. |
| | 2. <i>Identify corrections</i> : Identify splits, merges, moves, renames. |
| | 3. <i>Identify additions/exclusions</i> : Identify new or missing taxa. |
| | 4. <i>Overview changes</i> : Obtain a global view of changes. |
| | 5. <i>Summarize</i> : Obtain numerical understanding of change. |
| Query | 6. <i>Find inconsistencies</i> : Recognize violation of rules (e.g. repeated names) |
| | 7. <i>Filter</i> : Find cases that satisfy certain conditions. |
| | 8. <i>Retrieve details</i> : Retrieve the attributes of a particular concept. |
| | 9. <i>Focus</i> : Navigate and see the information in detail. |
| Edit | 10. <i>Edit</i> : Make changes to the taxonomies. |

Figure 1

Agglomeration method implementation.

Taxonomies are agglomerated into one hierarchical structure. Changes are indicated by relationships between the two taxonomies. In order to distinguish to which taxonomy the taxon belongs to, a dual use of color was introduced. For each taxon's specific change, light nuanced nodes indicate that the taxa belongs to the taxonomy of origin and the darker nuanced nodes indicate that they belong to the taxonomy of destination. Through the colored toggle buttons on the menu, users can visualize either one or several types of changes at once. Users can select a specific taxon in order to visualize its changes.

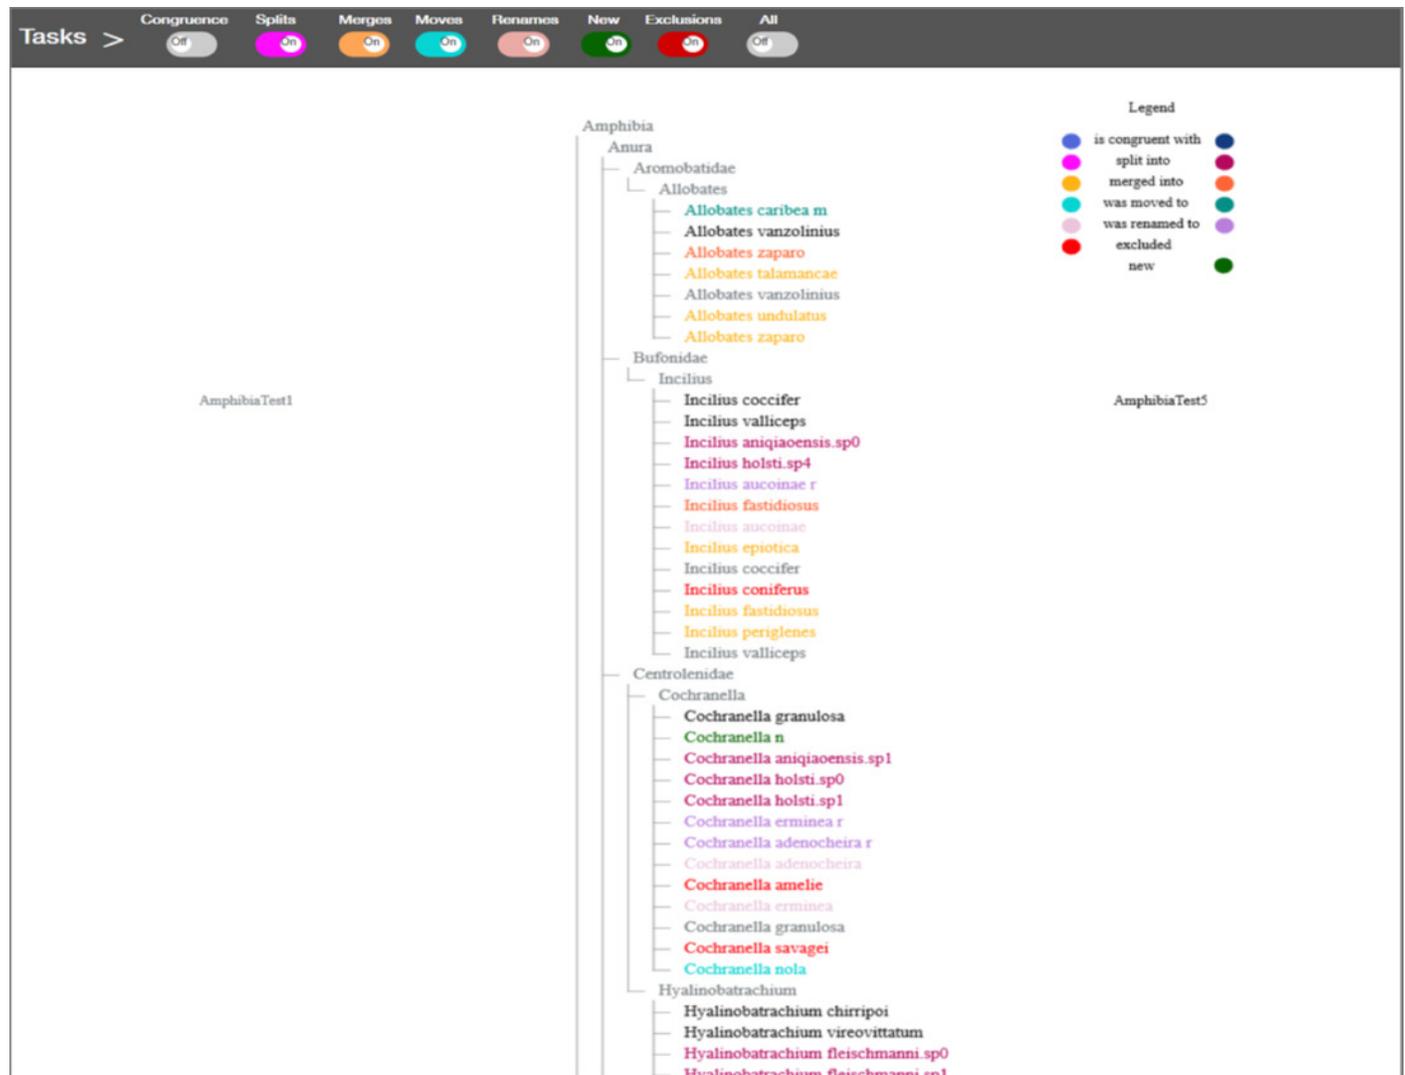

Figure 2

Animation method implementation.

Changes are presented through animation. Besides the common toggle buttons on the main menu for all methods, the animation method includes a play/stop button, a speed slider, and a button that controls whether the animation will present the changes either one by one or simultaneously. During animation, taxa moves from the origin taxonomy on the left side to the destination taxonomy on the right, displaying the transformation. Through the colored toggle buttons on the menu, users can animate either one or several types of changes at once. Users can select a specific taxon in order to visualize its changes.

Table 4(on next page)

Comparison of participants' effectiveness using Cochran's Q test.

Each row corresponds to a task-performing exercise. Each cell of the row contains the results of the participants' effectiveness with each method for the evaluated exercise, as well as the chi-square and p-value resulting from the Cochran's Q test. Resulting less-effective methods for each exercise are shaded in orange.

| Exercise | Frequency (%) | | | | χ^2 | p-value |
|---|-----------------|-----------------|-----------------|-----------------|---------------|--------------|
| | Agg | Ani | Edg | Mat | | |
| 1. Which is the most common type of change? | 9 (75) | 11 (92) | 1 (8) | 11 (92) | 25.500 | 0.000 |
| 2. Into what taxa was taxon "t" split? | 11 (92) | 10 (83) | 11 (92) | 11 (92) | 3.000 | 0.392 |
| 3. Which species was split most? | 4 (33) | 7 (58) | 12 (100) | 11 (92) | 17.571 | 0.001 |
| 4. Was species "s" merged with any other species? | 11 (92) | 11 (92) | 12 (100) | 12 (100) | 3.000 | 0.392 |
| 5. With which other species was taxon "t" merged? | 12 (100) | 11 (92) | 12 (100) | 12 (100) | 3.000 | 0.392 |
| 6. Which is the new name of taxon "t"? | 12 (100) | 12 (100) | 12 (100) | 12 (100) | – | – |
| 7. Which was the previous name of "t"? | 11 (92) | 12 (100) | 12 (100) | 12 (100) | 3.000 | 0.392 |
| 8. Which species were moved to genus "g"? | 5 (42) | 12 (100) | 12 (100) | 12 (100) | 21.000 | 0.000 |
| 9. Which family has the most species added? | 11 (92) | 11 (92) | 12 (100) | 12 (100) | 2.000 | 0.572 |
| 10. Genus to which more than one species were excluded? | 11 (92) | 12 (100) | 12 (100) | 12 (100) | 3.000 | 0.392 |
| 11. What types of changes occurred to taxon "t"? | 6 (50) | 9 (75) | 11 (92) | 12 (100) | 9.692 | 0.021 |
| 12. Identify which genus shows most changes. | 2 (17) | 7 (58) | 7 (58) | 7 (58) | 10.714 | 0.013 |
| Effectiveness (overall) | 105 (73) | 125 (87) | 126 (88) | 136 (94) | 40.480 | 0.000 |

Figure 4

Matrix method implementation.

The two taxonomies are arranged along the horizontal and vertical axes of the matrix. Changes between the two comparable taxonomies are highlighted through the color-coded cells. Through the colored toggle buttons on the menu, users can visualize either one or several types of changes at once. Users can select a specific taxon in order to visualize its changes.

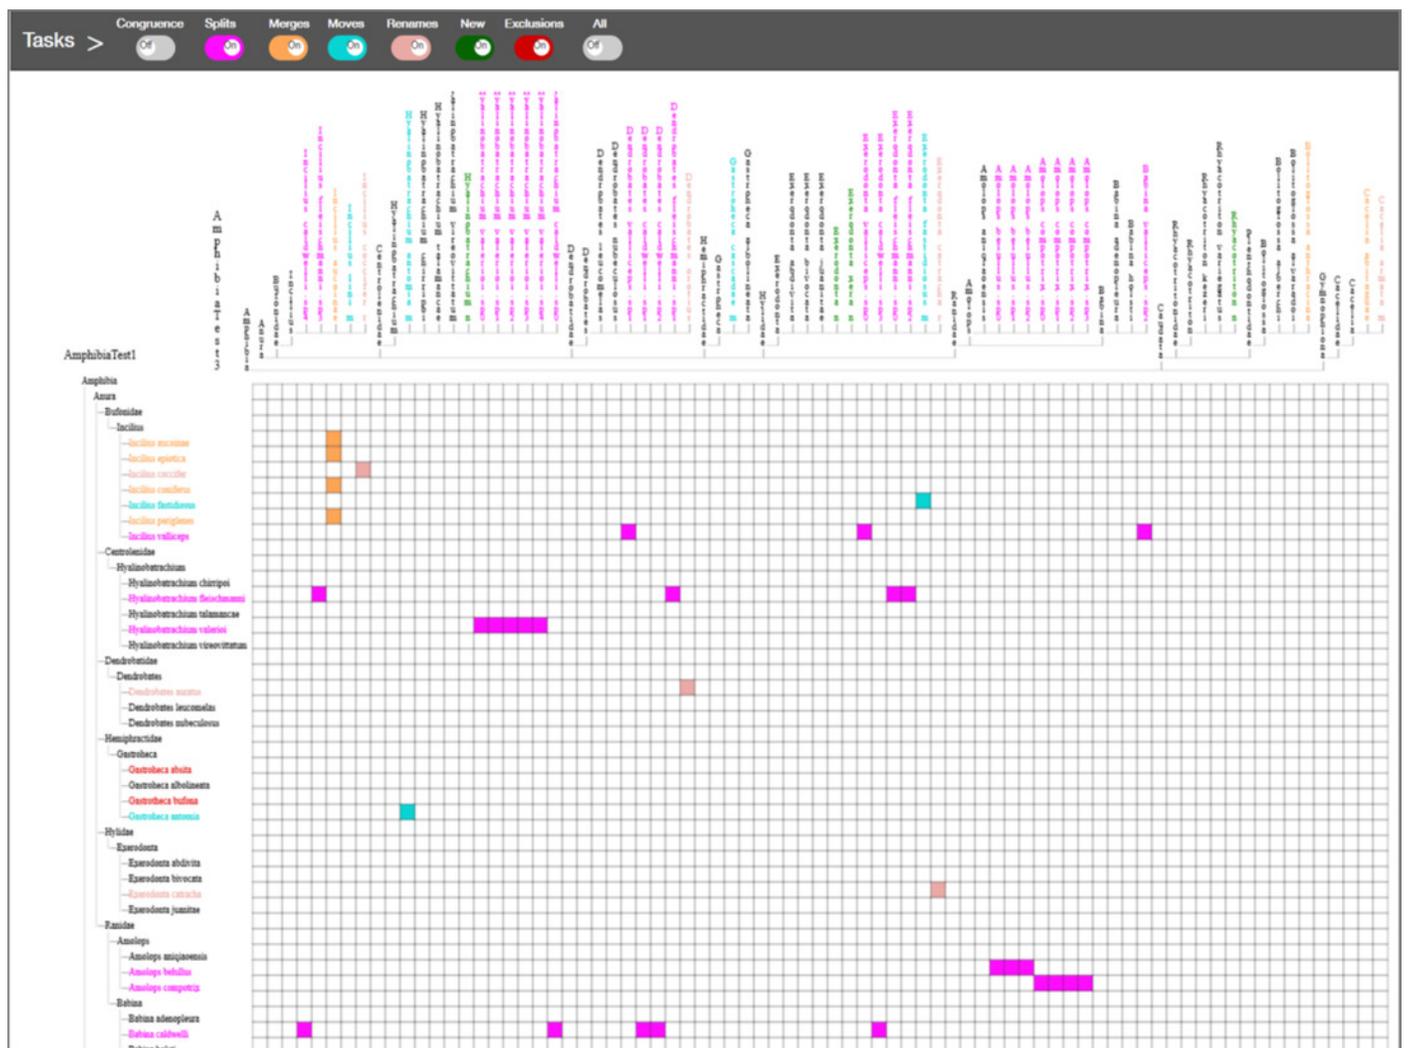

Table 5 (on next page)

Comparison of participants' satisfaction using Friedman test.

Each row corresponds to a task-performing exercise. Each cell of the row contains the results of the participants' satisfaction level with each method for the evaluated exercise, as well as the chi-square and p-value resulting from the Friedman test. Higher satisfaction level is shaded in green and less satisfaction level in orange.

| Question How good do you think is each method in order to ... | Median | | | | χ^2 | p-value |
|---|--------|------|------|------|----------|---------|
| | Agg | Ani | Edg | Mat | | |
| 1e- ... identify the most common type of change? | 2.08 | 1.79 | 3.29 | 2.83 | 12.588 | 0.006 |
| 3e- ... identify splits? | 1.50 | 1.50 | 3.79 | 3.21 | 33.055 | 0.000 |
| 5e- ... identify merges? | 2.00 | 1.71 | 3.71 | 2.58 | 20.050 | 0.000 |
| 7e- ... identify renaming of taxa? | 2.13 | 1.50 | 3.67 | 2.71 | 21.559 | 0.000 |
| 8e- ... identify moves? | 1.54 | 1.88 | 3.83 | 2.75 | 24.295 | 0.000 |
| 9e- ... identify new species added? | 2.75 | 2.63 | 2.96 | 1.67 | 9.539 | 0.023 |
| 10e- ... identify excluded taxa? | 2.67 | 1.88 | 2.79 | 2.67 | 7.062 | 0.070 |
