Currently, the new coronavirus disease (COVID-19) is one of the biggest health crises threatening the world. Automatic detection from computed tomography (CT) scans is a classic method to detect lung infection, but it faces problems such as high variations in intensity, indistinct edges near lung infected region and noise due to data acquisition process. Therefore, this paper proposes a new COVID-19 pulmonary infection segmentation depth network referred as the ADID-UNET (Attention Gate-Dense Network- Improved Dilation Convolution-UNET). The dense network replaces convolution and maximum pooling function to enhance feature propagation and solves gradient disappearance problem. An improved dilation convolution is used to increase the receptive field of the encoder output to further obtain more edge features from the small infected regions. The integration of attention gate into the model suppresses the background and improves prediction accuracy. The experimental results show that the ADID-UNET model can accurately segment COVID-19 lung infected areas, with performance measures greater than 80% for metrics like Accuracy, Specificity and Dice Coefficient (DC). Further when compared to other state-of-the-art architectures, the proposed model showed excellent segmentation effects with a high DC and F1 score of 0.8031 and 0.82 respectively.

ABSTRACT

Currently, the new coronavirus disease (COVID-19) is one of the biggest health crises threatening the world. Automatic detection from computed tomography (CT) scans is a classic method to detect lung infection, but it faces problems such as high variations in intensity, indistinct edges near lung infected region and noise due to data acquisition process. Therefore, this paper proposes a new COVID-19 pulmonary infection segmentation depth network referred as the ADID-UNET (Attention Gate-Dense Network- Improved Dilation Convolution-UNET). The dense network replaces convolution and maximum pooling function to enhance feature propagation and solves gradient disappearance problem. An improved dilation convolution is used to increase the receptive field of the encoder output to further obtain more edge features from the small infected regions. The integration of attention gate into the model suppresses the background and improves prediction accuracy. The experimental results show that the ADID-UNET model can accurately segment COVID-19 lung infected areas, with performance measures greater than 80% for metrics like accuracy, specificity and Dice Coefficient (DC). Further when compared to other state-of-the-art architectures, the proposed model showed excellent segmentation effects with a high DC and F1 score of 0.8031 and 0.82 respectively.

1 INTRODUCTION

COVID-19 has caused a worldwide health crisis. The World Health Organization (WHO) announced COVID-19 as a pandemic on March 11, 2020. The clinical manifestations of COVID-19 range from influenza-like symptoms to respiratory failure (i.e. diffuse alveolar injury) and its treatment requires advanced respiratory assistance and artificial ventilation. According to the global case statistics from the Center for Systems Science and Engineering (CSSE) of Johns Hopkins University (JHU) (Wang et al., 2020) (updated August 30, 2020), 24,824,247 confirmed COVID-19 cases, including 836,615 deaths, have been reported so far with pronounced effect in more than 180 countries. COVID-19 can be detected and screened by Reverse Transcription Polymerase Chain Reaction (RT-PCR). However, the shortage of equipment and the strict requirements on the detection environment limit the rapid and accurate screening of suspected cases. Moreover, the sensitivity of RT-PCR is not high enough, resulting in a large number of false-negatives (Ai et al., 2020), which presents early detection and treatment of patients with presumed COVID-19 (Fang et al., 2020). As an important supplement to RT-PCR, CT scans clearly describe the characteristic lung manifestations related to COVID-19 (Chung et al., 2020), the early Ground Glass Opacity (GGO), and late lung consolidation are shown in Figure 1. Nevertheless, CT scans also show

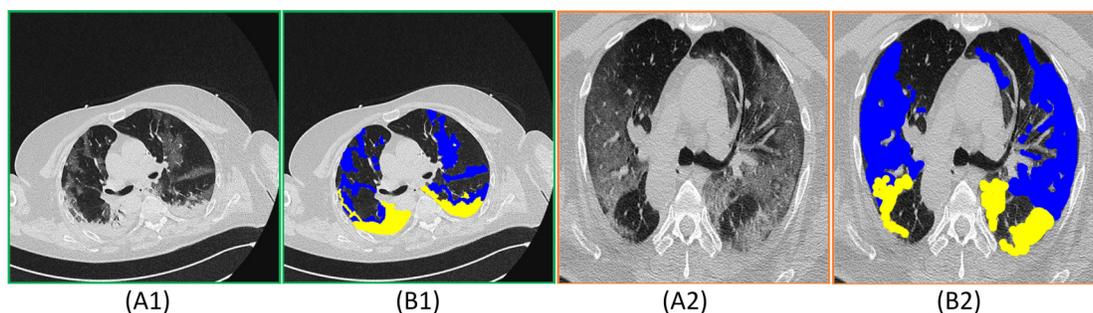

Figure 1. (A1) and (A2) represent the CT images and (B1) and (B2) correspond to the COVID-19 infected areas in CT axial section. Here the blue and yellow masks represent the Ground Glass Opacity (GGO) and the late lung consolidation segments respectively. The images were obtained from (Medseg.ai, 2020).

47 imaging features that are similar to other types of pneumonia, making it difficult to differentiate them.
48 Moreover, the manual depiction of lung infection is a tedious and time-consuming job, which is often
49 influenced by personal bias and clinical experience.

50

51 In recent years, deep learning has been gaining popularity in the field of medical imaging due to its
52 intelligent and efficient feature extraction ability (Kong et al., 2019; Ye et al., 2019), and has achieved
53 great success. An earliest classic example is the application of deep learning to children's chest X-rays
54 to detect and distinguish bacterial and viral pneumonia (Kermary DS, 2018; Rajaraman et al., 2018).
55 Also using deep learning methods have been applied to detect various imaging features of chest CT
56 images (Depeursinge et al., 2015; Anthimopoulos et al., 2016). Recently, researchers proposed to detect
57 COVID-19 infections in patients by radiation imaging combined with deep learning technology. Li et al.
58 (2020) proposed a simple Cov-Net deep learning network in combination with a deep learning algorithm,
59 which was used to distinguish COVID-19 and Community-Acquired Pneumonia (CAP) from chest CT
60 scans. Wang and Wong (2020) proposed Covid-Net to detect COVID-19 cases from chest X-ray images,
61 with an accuracy rate of 93.3%. The infection probability of COVID-19 Xu et al. (2020) was calculated
62 from CT scans by adopting a position-oriented attention model that presented accuracy close to 87%.
63 However, the above models rarely involved the segmentation of COVID-19 infection (Chaganti et al.,
64 2020; Shan et al., 2020). The challenges involved in segmentation include: **a)** variations in texture, size,
65 and position of the infected areas in CT scans. For example, some infection areas are small, which
66 easily lead to a high probability of false negatives in CT scans. **b)** The boundary of GGO is usually of
67 low contrast and fuzzy in appearance, which makes it difficult to distinguish from the healthy regions
68 during the segmentation process. **c)** The noise around the infected area is high, which greatly affects the
69 segmentation accuracy and **d)** finally the cost and time consumed in obtaining high-quality pixel-level
70 annotation of lung infection in CT scans is high. Therefore, most of the COVID-19 CT scan datasets are
71 focused on diagnosis, and only a few of them provide segmentation labels. However, with the passage of
72 time, the annotated datasets for the segmentation of COVID-19 pulmonary infection were released but
73 due to a lesser amount of data, the phenomenon of overfitting could cause problems while training thus
74 necessitating the need for more segmentation datasets and better algorithms for accurate results.

75 Therefore, to address the challenges stated above, we propose a new deep learning network called At-
76 tention Gate-Dense Network- Improved Dilation Convolution-UNET (ADID-UNET) for the segmentation
77 of COVID-19 from lung infection CT scans. Experimental results on a publicly available dataset illustrate
78 that the proposed model presents reliable segmentation results that are comparable to the ground truths
79 annotated by experts. Also, in terms of performance, the proposed model surpasses other state-of-the-art
80 segmentation models, both qualitatively and quantitatively.

81 Our contributions in this paper are as follows:

- 82 1. To address the problem that the gradient disappearance in the deep learning network pose, we employ
83 a dense network (Huang et al., 2017) instead of a traditional convolution and max-pooling operations.
84 The dense network extracts dense features and enhances feature propagation through the model.
85 Moreover, the training parameters of the dense network are less, which reduces the size and the

86 computational cost.

87 2. To increase the size of the respective field and to compensate for the problems due to blurry edges, an
88 improved dilation convolution (IDC) module is used to connect the encoder and decoder pipelines.
89 The IDC model increases the receptive field of the predicted region providing more edge information,
90 which enhances the edge recognition ability of the model.

91 3. Since the edge contrast of GGO is very low, we use the attention gate (AG) instead of simple cropping
92 and copying. This further improves the accuracy of the model to detect the infection areas by learning
93 the characteristics of the infected regions.

94 4. Due to the limited number of COVID-19 segmented datasets with segmentation labels, which is
95 less than the minimum number of samples required for training a complex model, we employ data
96 augmentation techniques and expand the dataset on the basis of the collected public datasets.

97 The rest of the paper is organized as follows: Section 2 describes the work related to the proposed
98 model. Section 3 introduces the basic structure of ADID-UNET. Details of the dataset, experimental
99 results and discussion are dealt with in section 4. Finally, section 5 presents the conclusion.

100 2 RELATED WORK

101 ADID-UNET model proposed in this paper is based on UNET (Ronneberger et al., 2015) architecture and
102 therefore, we will discuss the literature related to our work which includes: deep learning and medical
103 image segmentation, improvement of medical image segmentation algorithms, CT scan segmentation,
104 and application of deep learning in segmentation of COVID-19 lesions from lung CT scans.

105 2.1 Deep learning and medical image segmentation

106 In recent years, deep learning algorithms have become more mature leading to various artificial intelli-
107 gence (AI) systems based on deep learning algorithms being developed. Also, semantic segmentation
108 using deep learning algorithms (Oktay et al., 2018) has developed rapidly with applications in both natural
109 and medical images. Long et al. (2015) pioneered the use of a fully connected CNN (FCN) to present
110 rough segmentation outputs that were of the input resolution through fractionally strided convolution
111 process also referred as the upsampling or deconvolution. The model was tested on PASCAL VOC,
112 NYUDv2, and SIFT datasets and, presented a Mean Intersection of Union (M-IOU) of 62.7%, 34%,
113 39.5%, respectively. They also reported that upsampling, part of the in-network, was fast, accurate, and
114 provided dense segmentation predictions. Later through a series of improvements and extensions to
115 FCN (Ronneberger et al., 2015; Badrinarayanan et al., 2017; Xu et al., 2018), a symmetrical structure
116 composed of encoder and decoder pipelines, called UNET (Ronneberger et al., 2015), was proposed for
117 biomedical or medical image segmentation. The encoder structure predicted the segmentation area, and
118 then the decoder recovered the resolution and achieved accurate spatial positioning. Also, the UNET
119 used crop and copy operations for the precise segmentation of the lesions. Further, the model achieved
120 good segmentation performance at the International Symposium on Biomedical Imaging (ISBI) challenge
121 (Cardona et al., 2010) with the M-IOU of 0.9203. Moreover, an improved network referred as the SegNet
122 was proposed by Badrinarayanan et al. (2017). The model used the first 13 convolution layers of the
123 VGG16 network (Karen and Andrew, 2014) to form an encoder to extract features and predict segmen-
124 tation regions. Later by using a combination of convolution layers, unpooling and softmax activation
125 function in the decoder, segmentation outputs of input resolution were obtained. When tested with the
126 CamVid dataset (Brostow et al., 2009), the M-IOU index of SegNet was nearly 10% higher than that of
127 FCN (Long et al., 2015). Xu et al. (2018) regarded segmentation as a classification problem in which
128 each pixel was associated with a class label and designed a CNN network composed of three layers of
129 convolution and pooling, a fully connected layer (FC) and softmax function. The model of successfully
130 segmented three-dimensional breast ultrasound (BUS) image datasets was presented into four parts: skin,
131 fibroglandular tissue, mass, and fatty tissue and achieved a recall rate of 88.9%, an accuracy of 90.1%,
132 precision of 80.3% and F1 score of 0.844. According to the aforementioned literature, FCN (Long et al.,
133 2015) and their improved variants presented accurate segmentation results for both natural or medical
134 images. Therefore, the UNET and variants (Almajalid et al., 2019; Negi et al., 2020), due to its advantages
135 of fast training and high segmentation accuracy are widely used in the field of medical image segmentation.

136

137 2.2 Improvement of medical image segmentation algorithms

138 Medical images such as the ultrasound images are generally prone to speckle noise, uneven intensity
139 distribution, and low contrast between the lesions and the backgrounds which affect the segmentation
140 ability of the traditional UNET (Ronneberger et al., 2015) structure. Therefore, considerable efforts were
141 invested in improving the architecture. Xia and Kulis (2017) proposed a fully unsupervised deep learning
142 network called W-Net model that connects two UNETs to predict and reconstruct the segmentation results.
143 Schlemper et al. (2019) proposed an attention UNET network, which integrated attention modules into the
144 UNET (Ronneberger et al., 2015) model to achieve spatial positioning and subsequent segmentation. The
145 model presented a segmentation accuracy of 15% higher than the traditional UNET architecture. Zhuang
146 et al. (2019a) combined the goodness of the attention gate system and the dilation convolution module and
147 proposed a hybrid architecture referred as the RDA-UNET. By introducing residual network (He et al.,
148 2016) instead of traditional convolution layers they reported a segmentation accuracy of 97.91% towards
149 the extraction of lesions in breast ultrasound images. Also, the GRA-UNET (Zhuang et al., 2019b)
150 model included a group convolution module in-between the encoder and decoder pipelines to improve
151 the segmentation of the nipple region in breast ultrasound images. Therefore, from the literature, it can
152 be inferred that introducing additional modules like attention gate instead of traditional cropping and
153 copying, inclusion of dilation convolution to increase the receptive fields and use of residual networks
154 can favorably improve the accuracy of the segmentation model. However, these successful segmentation
155 models (Schlemper et al., 2019; Zhuang et al., 2019a; Xia and Kulis, 2017) were rarely tested with CT
156 scans, hence the next section concentrates on the segmentation of CT scans.

157 2.3 CT scan segmentation

158 CT imaging is a commonly used technology in the diagnosis of lung diseases since lesions can be
159 segmented more intuitively from the chest CT scans. The segmented lesion aid the specialist in the
160 diagnosis and quantification of the lung diseases (Gordaliza et al., 2018). In recent years, most of the
161 classifier models and algorithms based on feature extraction have achieved good segmentation results in
162 chest CT scans. Ye et al. (2009) proposed a shape-based Computer-Aided Detection (CAD) method where
163 a 3D adaptive fuzzy threshold segmentation method combined with chain code was used to estimate
164 infected regions in lung CT scans. In feature-based techniques, due to the low contrast between nodules
165 and backgrounds, the boundary discrimination is unclear leading to inaccurate segmentation results.
166 Therefore, many segmentation techniques based on deep learning algorithms have been proposed. Wang
167 et al. (2017) developed a central focusing convolutional neural network for segmenting pulmonary nodules
168 from heterogeneous CT scans. Jue et al. (2018) designed two deep networks (an incremental and dense
169 multiple resolution residually connected network) to segment lung tumors from CT scans by adding
170 multiple residual flows with different resolutions. Guofeng et al. (2018) proposed a UNET model to
171 segment pulmonary nodules in CT scans which improved the overall segmentation output through the
172 avoidance of overfitting. Compared with other segmentation algorithms such as graph-cut (Ye et al.,
173 2009), their model had better segmentation results with a Dice coefficient of 0.73. Recently, Peng et al.
174 (2020) proposed an automatic CT lung boundary segmentation method, called Pixel-based Two-Scan
175 Connected Component Labeling-Convex Hull-Closed Principal Curve method (PSCCL-CH-CPC). The
176 model included the following: **a)** the image preprocessing step to extract the coarse lung contour and
177 **b)** coarse to finer segmentation algorithm based on the improved principal curve and machine learning
178 model. The model presented good segmentation results with Dice coefficient as high as 96.9%. Agarwal
179 et al. (2020) proposed a weakly supervised lesion segmentation method for CT scans based on an
180 attention-based co-segmentation model (Mukherjee et al., 2018). The encoder structure composed of a
181 variety of CNN architectures that includes VGG-16 (Karen and Andrew, 2014), Res-Net101 (He et al.,
182 2016), and an attention gate module between the encoder-decoder pipeline, while decoder composed of
183 upsampling operation. The proposed method first generated the initial lesion areas from the Response
184 Evaluation Criteria in Solid Tumors (RECIST) measurements and then used co-segmentation to learn
185 more discriminative features and refine the initial areas. The paper reported a Dice coefficient of 89.8%.
186 The above literatures suggest that deep learning techniques are effective in segmenting lesions in lung CT
187 scans and many researchers have proposed different deep learning architectures to deal with COVID-19
188 CT scans. Therefore, in the next section we will further study their related works.

189 2.4 Application of deep learning in segmentation of COVID-19 lesions from lung CT 190 scans

191 In recent months, COVID-19 has become a hot topic of concern all over the world and CT imaging is
192 considered to be a convincing method to detect COVID-19. However, due to the limited datasets and the
193 time and labor involved in annotations, segmentation datasets related to COVID-19 CT scans are less
194 readily available. But, many researchers have still proposed advanced methods to deal with COVID-19
195 diagnosis, which also includes segmentation techniques (Fan et al., 2020; Wang et al., 2020; Yan et al.,
196 2020; Zhou et al., 2020; Elharrouss et al., 2020; Chen et al., 2020). On the premise of insufficient datasets
197 with segmentation labels, the Inf-Net network proposed by Fan et al. (2020), combined a semi-supervised
198 learning model and FCN8s network (Long et al., 2015) with implicit reverse attention and explicit
199 edge attention mechanism to improve the recognition rate of infected areas. The model successfully
200 segmented COVID-19 infected areas from CT scans and reported a sensitivity and accuracy of 72.5%
201 and 96.0%, respectively. Elharrouss et al. (2020) proposed an encoder-decoder-based CNN method
202 for COVID-19 lung infection segmentation based on a multi-task deep-learning based method, which
203 overcame the shortage of labeled datasets, and segmented lung infected regions with a high sensitivity
204 of 71.1%. Wang et al. (2020) proposed a noise-robust COVID-19 pneumonia lesions segmentation
205 network which included a noise-robust dice loss function along with convolution function, residual
206 network, and Atrous Spatial Pyramid Pooling (ASPP) module. The model was referred as Cople-Net
207 presented automatic segmentation of COVID-19 pneumonia lesions from CT scans. The method proved
208 that the proposed new loss function was better than the existing noise-robust loss functions such as
209 Mean absolute error (MAE) loss (Ghosh et al., 2017) and Generalized Cross-Entropy (GCE) loss (Zhang
210 and Sabuncu, 2018) and achieved a Dice coefficient and Relative Volume Error (RVE) of 80.72% and
211 15.96%, respectively. Yan et al. (2020) employed an encoder-decoder deep CNN structure composed
212 of convolution function, Feature Variation (FV) module (mainly contains convolution, pooling, and
213 sigmoid function), Progressive Atrous Spatial Pyramid Pool (PASPP) module (including convolution,
214 dilation convolution, and addition operation) and softmax function. The convolution function obtained
215 features, FV block enhanced the feature representation ability and the PASPP was used between encoder
216 and decoder pipelines compensated for the various morphologies of the infected regions. The model
217 achieved a good segmentation performance with a Dice coefficient of 0.726 and a sensitivity of 0.751
218 when tested on the COVID-19 lung CT scan datasets. Zhou et al. (2020) proposed an encoder-decoder
219 structure based UNET model for the segmentation of the COVID-19 lung CT scan. The encoder structure
220 was used to extract features and predict rough lesion areas which composed convolution function and
221 Res-dil block (combines residual block (He et al., 2016) and dilation convolution module). The decoder
222 pipeline was used to restore the resolution of the segmented regions through the upsampling and the
223 attention mechanism between the encoder-decoder framework to capture rich contextual relationships
224 for better feature learning. The proposed method can achieve an accurate and rapid segmentation on
225 COVID-19 lung CT scans with a Dice coefficient, sensitivity, and specificity of 69.1%, 81.1%, and 97.2%,
226 respectively. Further, Chen et al. (2020) proposed a residual attention UNET for automated multi-class
227 segmentation of COVID-19 lung CT scans, which used residual blocks to replace traditional convolutions
228 and upsampling functions to learn robust features. Again, a soft attention mechanism was applied to
229 improve the feature learning capability of the model to segment infected regions of COVID-19. The
230 proposed model demonstrates a good performance with a segmentation accuracy of 0.89 for lesions in
231 COVID-19 lung CT scans. Therefore, the deep learning algorithms are helpful in segmenting the infected
232 regions from COVID-19 lung CT scans which aid the clinicians to evaluate the severity of infection (Tang
233 et al., 2020), large-scale screening of COVID-19 cases (Shi et al., 2020) and quantification of the lung
234 infection (Ye et al., 2020). Table 1 summarizes the deep learning-based segmentation techniques available
235 for COVID-19 lung infections.

236 3 METHODS

237 In this section, we first introduce the proposed ADID-UNET network with detailed discussion on the
238 core network components including dense network, improved dilation convolution, and attention gate
239 system. To present realistic comparisons, experimental results are presented at each subsection to illustrate
240 the performance and superiority of the model after adding core components. Further in Section 4 we
241 have presented a summary of the % improvements achieved when compared to the traditional UNET

242 architecture.

Literature	Data Type	Dataset	Technique	Segmentation Results
Fan et al. (2020)	CT Scan	100 CT images	Semi supervised CNN FCN8s network	73.9%(DC) 96.0%(S_p)
Wang et al. (2020)	CT Scan	558 CT images	Residual connection CNN	80.7%(DC) 16.0%(RVE)
Yan et al. (2020)	CT Scan	21,658 CT images	Deep CNN	72.6%(DC) 75.1%(S_{en})
Zhou et al. (2020)	CT Scan	100 CT images	Attention mechanism Res-Net,dilation convolution	69.1%(DC) 81.1%(S_{en})
Elharrouss et al. (2020)	CT Scan	100 CT images	Encoder-decoder- based CNN	78.6%(Dice) 71.1%(S_{en})
Chen et al. (2020)	CT Scan	110 CT images	Encoder-decoder- basedCNN	83.0%(DC) 89.0%(ACC)
Xu et al. (2020)	CT Scan	110 CT images	CNN	86.7%(ACC) 83.9%(F1)
Shuai et al. (2020)	CT Scan	670 CT images	CNN	73.1%(ACC) 67.0%(S_p)

Table 1. The summary of various deep learning algorithms for COVID-19 lung CT scans and the segmentation results. RVE, ACC, DC, S_{en} , S_p and F1 represent relative volume error, accuracy, Dice coefficient, sensitivity, specificity and F1 score, respectively.

243 3.1 ADID-UNET Architecture

244 ADID-UNET is based on UNET (Ronneberger et al., 2015) architecture with the following improvements:
 245 (a) The dense network proposed by Huang et al. (2017) is used in addition to the convolution modules of
 246 encoder and decoder structures, (b) an improved dilation convolution (IDC) is introduced between the
 247 frameworks, and (c) the attention gate (AG) system is used instead of the simple cropping and copying
 248 operations. The structure of ADID-UNET is shown in Figure 2. Here f_{en} , f_{upn} , f_{idc} describe the features
 249 at the n -th layer of the encoder, decoder, and IDC modules, respectively.

250 When COVID-19 CT scans are presented to the encoder, the first four layers (each layer has con-
 251 volutions, rectification, and max pooling functions) extract features (f_1 to f_4) that are passed to dense
 252 networks. Here dense networks are used instead of convolution and max-pooling layers to further enhance
 253 the features (f_5 to f_6) and in Section 3.2, we elaborate the need for the dense network and present
 254 experimental results to prove its significance. Next, an improved dilation convolution module referred as
 255 the IDC model, is used between the encoder-decoder structure to increase the receptive field and gather
 256 detailed edge information that assists in extracting the characteristic. The module accepts the feature f_6
 257 from the dense networks and after improvement, present f_{idc} them as inputs to the decoder structure. To
 258 ensure consistency in the architecture and to avoid losing information, the decoder mirrors the encoder
 259 with two dense networks that replace the first two upsampling operations. Further for the better use of the
 260 context information between the encoder-decoder pipeline, the AG model is used instead of cropping and
 261 copying operations, which aggregates the corresponding layer-wise encoder features with the decoder and
 262 presents it to the subsequent upsampling layers. Likewise, the decoder framework presents upsampled
 263 features f_{up1} to f_{up6} and final feature map (f_{up6}) is presented to the sigmoid activation function to predict
 264 and segment the COVID-19 lung infected regions. The following section explains the components of
 265 ADID-UNET in detail.

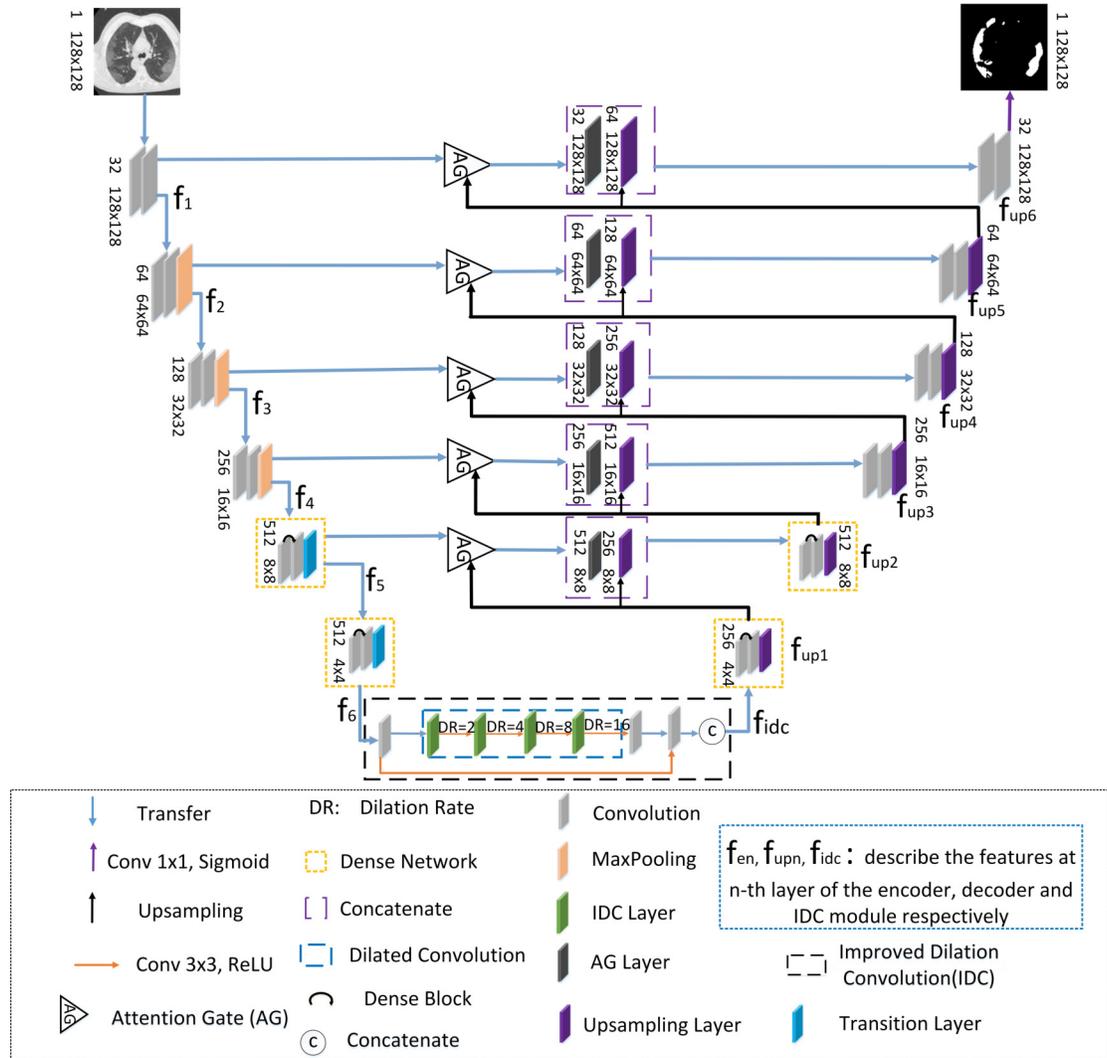

Figure 2. The structure of the ADID-UNET network.

266 3.2 Dense Network

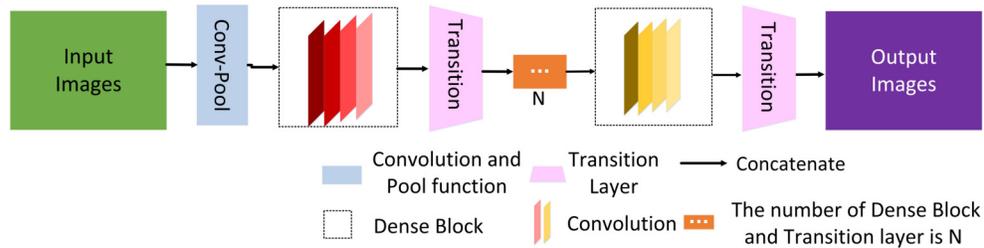

267 It was presumed that with the increase of network layers, the learning ability of the network will gradually
 268 improve, but during the training, for deep networks, the gradient information that is helpful for the
 269 generalization may disappear or expand excessively. In literature, the problem is referred as vanishing or
 270 explosion of the gradient. As the network begins to converge, due to the disappearance of the gradient
 271 the network saturates, resulting in a sharp decline in network performance. Therefore, Zhuang et al.
 272 (2019a) introduced residual units proposed by He et al. (2016) into UNET structure to avoid performance
 273 degradation during training. The residual learning correction scheme to avoid performance degradation is
 274 described in (1):

$$y = G(x, \{F_i\}) + x \quad (1)$$

275 Here x and y are the input and output vectors of the residual block, F_i is the weight of the corresponding
 276 layer. The function $G(x, \{F_i\})$ is a residue when added to x , avoids vanishing gradient problems, and
 277 enables efficient learning.

278 From (1) the summation of $G(x, \{F_i\})$ and x in Res-Net (He et al., 2016) avoids the vanishing
 279 gradient problems but forwarding the gradient information alone to the preceding layers may hinder the
 280 information flow in the network and the recent work by (Huang et al., 2016) illustrated that of Res-Nets
 281 discard features randomly during training. Moreover, Res-Nets include large number of parameters,

282 which increases the training time. To solve this problem, Huang et al. (2017) proposed a dense network
 283 (as shown in Figure 3), which directly connects all layers, and thus skillfully obtains all features of the
 previous layer without convolution. The dense network is mainly composed of convolution layers, pooling

284 **Figure 3.** Schematic diagram of the dense network.
 285 function, multiple dense blocks, and transition layers. Let us consider a network with L layers, and each
 286 layer implements a nonlinear transformation H_i . Let x_0 represent the input image, i represents layer i , x_{i-1}
 287 is the output of layer $i-1$. H_i can be a composite operation, such as batch normalization (BN), rectified
 288 linear function (RELU), pooling, or convolution functions. Generally, the output of traditional network in
 289 layer i is as follows:

$$x_i = H_i \times (x_{i-1}) \quad (2)$$

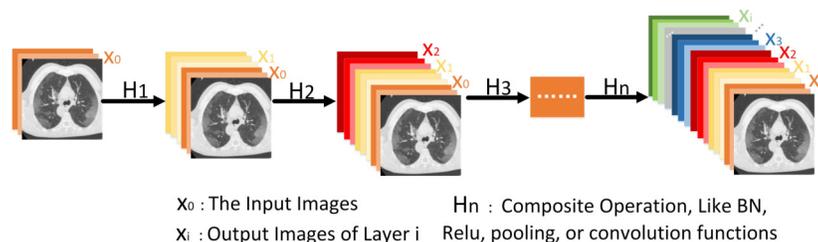

290 For the residual network, only the identity function from the upper layer is added:

$$x_i = H_i \times (x_{i-1}) + x_{i-1} \quad (3)$$

291 For a dense network, the feature mapping x_0, x_1, \dots, x_{i-1} of all layers before layer i is directly connected,
 292 which is represented by equation (4):

$$x_i = H_i \times ([x_0, x_1, \dots, x_{i-1}]) \quad (4)$$

293 where $[x_0, x_1, \dots, x_{i-1}]$ denotes the cascade of characteristic graphs and \times represents the multiplication
 294 operation. Figure 4 shows the forward connection mechanism of the dense network where the output of
 layers is connected directly to all previous layers.

295 **Figure 4.** It is more intuitive to understand the forward connection mode of a dense network. The
 296 output x_i includes the input from x_0, x_1, \dots, x_{i-1} .

297 Generally, a dense network is composed of several dense blocks and transition layers. Here we only
 298 use two dense blocks and transition layers to form simple dense networks. Using equation (5) to express
 the dense block:

$$\gamma = \alpha([x_0, x_1, \dots, x_{i-1}], \beta_i) \quad (5)$$

299 where $[x_0, x_1, \dots, x_{i-1}]$ denotes the cascade of characteristic graphs, β_i is the weight of the corresponding
 300 layer. In the ADID-UNET model proposed in this paper, the feature f_4 (refer to Figure 2) is fed to the
 301 transition layer, which is mainly composed of BN, RELU, and average pooling operation. Later the feature
 302 is batch standardized and rectified before convolving with a 1×1 kernel function. Again, the filtered
 303 outputs go through the same operation and are convoluted with 3×3 kernel, before concatenating with the
 304 input feature f_4 . The detailed structure of the two dense blocks and transition layers used in the encoder

305 structure is shown in Figure 5 (A). Here w , h correspond to the width and height of the input, respectively,
 306 and b represents the number of channels. Besides, s represents the step size of the pooling operation, n
 307 represents the number of filtering operations performed by each layer. In our model, n takes values 32,
 308 64, 128, 256, and 512. It should be noted that the output of the first dense layer is the aggregated result
 309 of 4 convolution operations ($4 \times n$), which is employed to emphasize the features learning by reducing
 310 the loss of features. In the decoding structure, to restore the resolution of the predicted segmentation, a
 311 traditional upsampling layer of the UNET (Ronneberger et al., 2015) is used instead of the transition layer.
 The detailed structure is shown in Figure 5 (B).

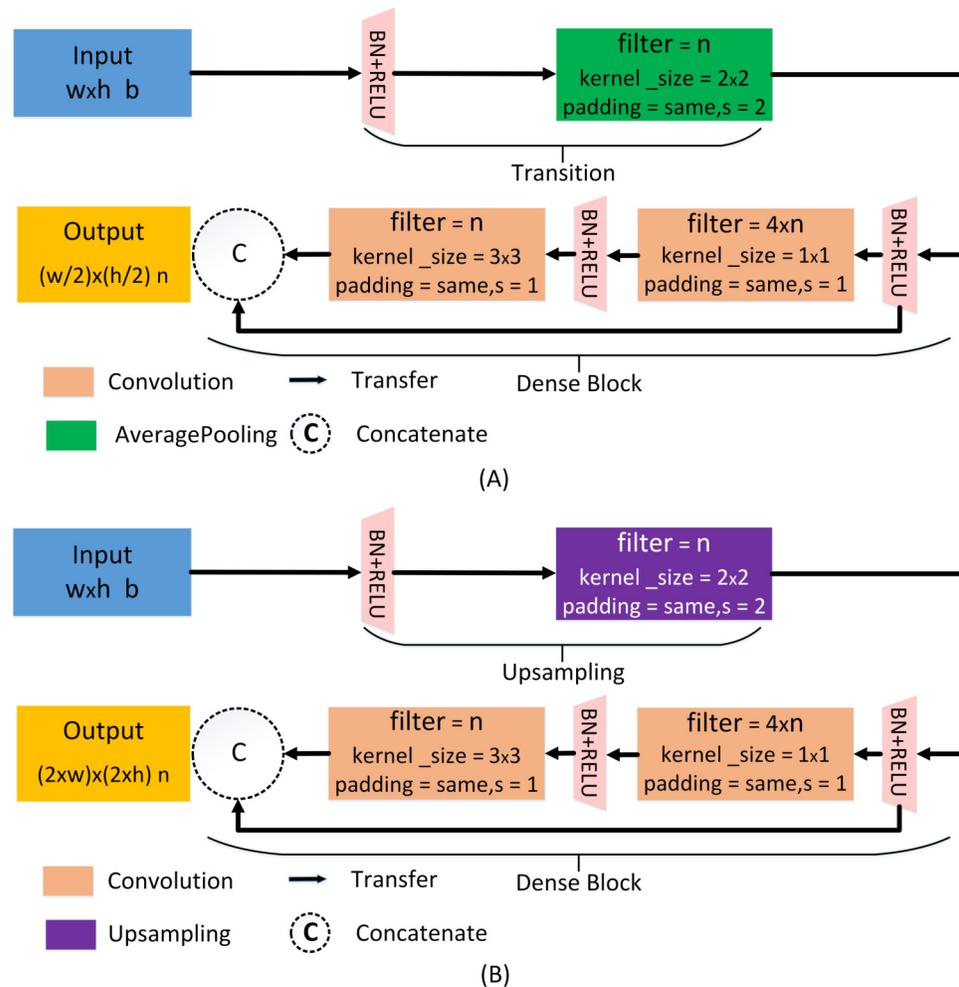

Figure 5. Dense network for encoder and decoder pipelines. (A) The dense network of the encoder pipeline. (B) The dense network of the decoder pipeline. Here, w , h , b , s , and n correspond to the width and height of the input, the number of channels, the step size of the pooling operation, and the number of filtering operations performed by each layer, respectively. For layers 6, 5, 4, 3, 2, 1, the values of n are 512, 512, 256, 128, 64, and 32, respectively.

312
 313 For the proposed network, we use only two dense networks mainly **a)** to reduce the computation costs
 314 and **b)** experiments with different layers of dense networks suggest that the use of two dense networks was
 315 sufficient since the segmentation results were accurate and comparable to the ground truth. Figure 6 and
 316 Table 2 illustrate the qualitative and quantitative comparisons with different numbers of dense network in
 317 the encoder-decoder framework.

318
 319 From the analysis of results in Figure 6 and Table 2, it is found that the effect of using two dense
 320 networks in the model is obvious and can present accurate segments of the infected areas that can be
 321 inferred directly from the qualitative and quantitative metrics.

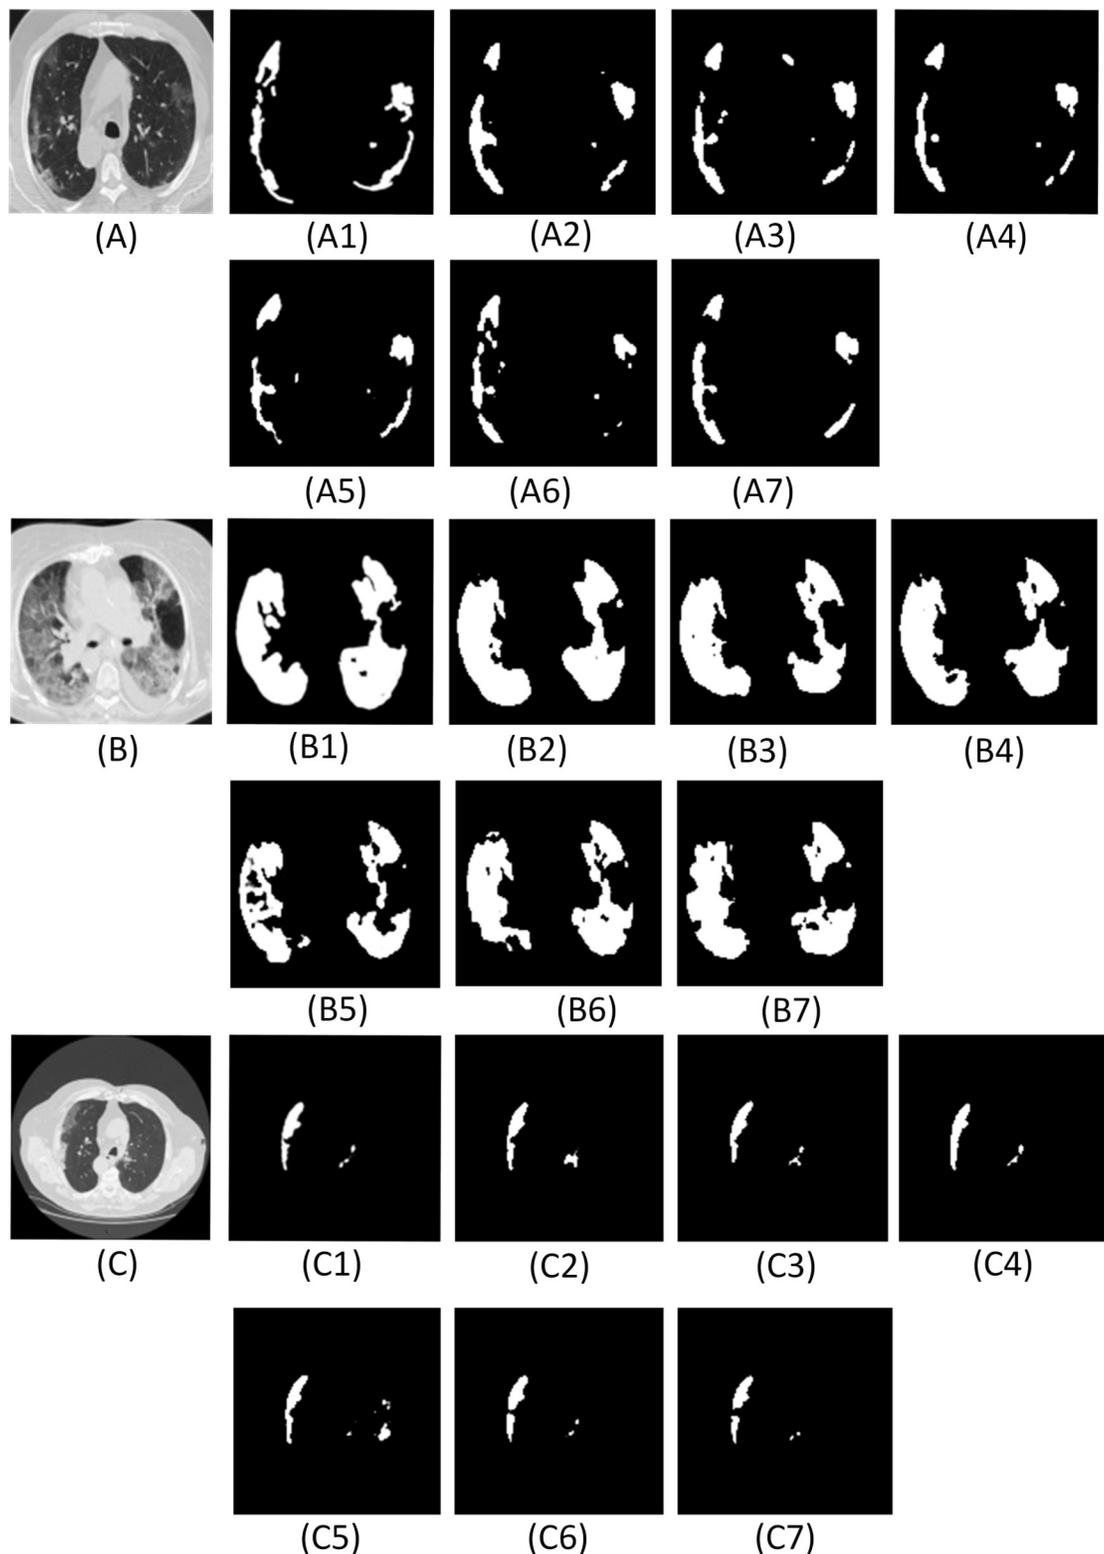

Figure 6. Results of adding different numbers of dense networks. Here (A)—(C) are the CT scans, (A1), (B1), (C1) are the ground truth, (A2)—(A7), (B2)—(B7), (C2)—(C7) are the segment results from UNET, Num_1 , Num_2 , Num_3 , Num_4 and Res-Net, respectively. $Num_1 \sim Num_4$ denotes the number of dense networks used in the encoder and decoder pipelines. Res-Net refers to the network where convolution operations are replaced by the residual network (He et al., 2016). UNET (Ronneberger et al., 2015) denotes the traditional architecture without dense networks.

322 Moreover, with high accuracy and a good Dice coefficient, the choice of two dense networks is the
 323 best choice in the encoder decoder pipeline. Also, using two dense networks in place of traditional
 324 convolutions or residual networks enable global feature propagation, encourage feature reuse, and also
 325 solve the gradient disappearance problems associated with deep networks thereby significantly improving
 326 the segmentation outcomes.

Number of Dense Network	ACC	DC	S_{en}	S_p	P_c	AUC	F1	S_m	E_α	MAE
Num_1	0.9696	0.7971	0.8011	0.9958	0.8290	0.9513	0.8129	0.8411	0.9315	0.0088
Num_2	0.9700	0.8011	0.8096	0.9966	0.8596	0.9492	0.8184	0.8528	0.9394	0.0083
Num_3	0.9686	0.7569	0.7546	0.9957	0.8200	0.9334	0.7806	0.8349	0.9379	0.0104
Num_4	0.9699	0.7869	0.7579	0.9961	0.8485	0.9495	0.8241	0.8341	0.9348	0.0090
UNET	0.9696	0.7998	0.8052	0.9957	0.8247	0.9347	0.8154	0.8400	0.9390	0.0088
Res-Net	0.9698	0.8002	0.7978	0.9962	0.8344	0.9504	0.8180	0.8415	0.9352	0.0094

Table 2. Quantitative comparisons with respect to ground truth for different dense layers included the UNET (Ronneberger et al., 2015) and Res-Net (He et al., 2016) architecture. ACC, DC, S_{en} , S_p , P_c , AUC, F1, S_m , E_α and MAE represent accuracy, Dice coefficient, sensitivity, specificity, precision, the area under the curve, F1 score, structural metric, enhancement alignment meter and mean absolute error, respectively.

327 3.3 Improved dilation convolution

328 Since the encoder pipeline of the UNET structure is analogous to the traditional CNN architecture, the
 329 pooling operations involved at each layer propagate either the maximum or the average characteristics
 330 of the extracted features, hence connecting the encoder outputs directly to decoder, thus limiting the
 331 segmentation accuracy of the network. The RDA-UNET proposed by Zhuang et al. (2019a) utilized a
 332 dilation convolution (DC) module between the encoder-decoder pipeline to increase the receptive field
 333 and further learn the boundary information accurately. Also, the DC module is often used in many variant
 334 UNETs (Chen et al., 2019; Yu and Koltun, 2015) to improve the receptive field, hence, we use the DC
 335 module and introduce additional novelty in the DC module.

336 Equation (6) describes the DC operation between the input image $f(x, y)$ and the kernel $g(i, j)$.

$$p(x, y) = \alpha \left\{ \sum_{i, j} f(x + i \times r, y + j \times r) \times g(i, j) + k \right\} \quad (6)$$

337 where α is the RELU function, k is a bias unit, (i, j) and (x, y) denote the coordinates of the kernel and
 338 those of the input images respectively, and r is the dilation rate that controls the size of receptive fields.
 339 The size of the receptive field obtained can be expressed as follows:

$$N = ((k_{-f_{size}} + 1) \times (r - 1) + k_{-f_{size}}) \quad (7)$$

340 where $k_{-f_{size}}$ is the convolution kernel size, r is the convolution rate of the dilation and N is the size of the
 341 receptive field. As shown in Figure 7.

342 Based on our experimental analysis we understand that DC module has a pronounced effect in ex-
 343 tracting information for larger objects or lesions and considering that most of the early ground-glass
 344 opacity (GGO) or late lung consolidation lesions have smaller areas, we present an improved dilation
 345 convolution (IDC) module between the encoder-decoder framework to accurately segment smaller regions.
 346

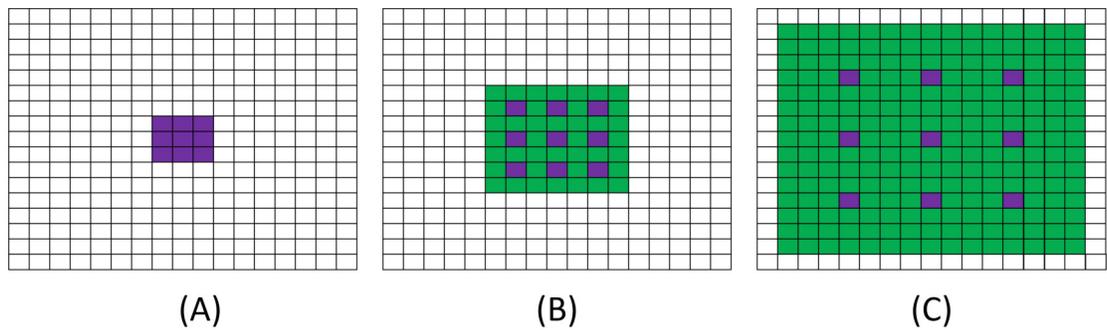

Figure 7. Schematic diagram of dilation convolution. (A) It shows the visual field effect of the classical 3×3 convolution kernel, covering 3×3 field of view each time (purple part of figure (A)); (B) corresponds to 3×3 with $r = 2$. Though the size of the convolution kernel is still 3×3 , but the receptive field of convolution kernel is increased to 7×7 (purple and green parts in figure (B)); (C) corresponds to 3×3 with $r = 3$ and a receptive field of 15×15 .

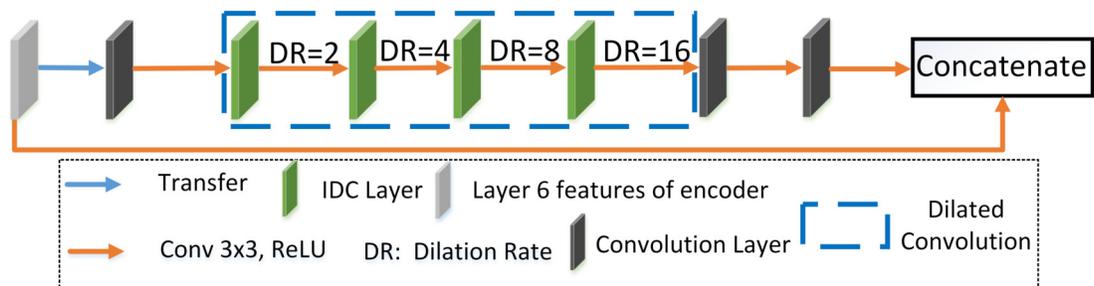

Figure 8. Improved dilation Convolution (IDC).

Method	Total Parameters	Trainable Parameters	Non-trainable Parameters	Train Time epoch/(s)	Test Time (s)
DD-UNET	56,223,034	56,190,272	32,762	145	8
DID-UNET	52,162,362	52,132,416	29,946	135	3

Table 3. Comparison results of the number of parameters of the UNET model with dense network incorporating either improved dilation convolution module (IDC) or dilation convolution module. Here DID-UNET refers to the inclusion of dense networks and IDC module and DD-UNET denotes dense networks and traditional dilation convolution added to the UNET structure.

347 Figure 8 illustrates the IDC module that consists of several convolution functions with different
 348 dilation rates and rectified linear functions (RELU). Our improvements are as follows: **a)** combining
 349 single strided convolution operations and dilated convolutions with dilation rate such as 2, 4, 8, and 16,
 350 respectively. The above combination helps in the extraction of features from both smaller and larger
 351 receptive fields thus assisting in the isolation of the small infected COVID-19 regions seen in lung CT
 352 scans and **b)** referring to the idea of the dense network (Huang et al., 2017), we concatenate the input
 353 of the IDC module to its output and use the information of input features to further enhance feature
 354 learning. The input of IDC module is the rough segmentation regions obtained by encoder structure.
 355 The combination of the original segmentation region features and the accurate features extracted by
 356 IDC module not only avoids the loss of useful information, but also provides accurate input for the
 357 decoding pipeline, which is conducive to improve the segmentation accuracy of the model. As the inputs
 358 advance (left to right in Figure 8), they get convolved with a 3×3 kernel of convolution layers and
 359 the dilation rate of IDC is 2, 4, 8, and 16, respectively. From the comparative experiments with the
 360 traditional DC model (the dilation rate is the same for both the models), we find that the computational cost
 361 and computation time required for the IDC module is less than that of the DC module, as shown in Table 3.
 362

363 From Figure 9 and Table 4, it is found that the use of layers with convolution and smaller dilation rates
 364 at the end along with others ensures the cumulative extraction of features from both smaller and larger
 365 receptive fields thus assisting in the isolation of the small infected COVID-19 regions seen in lung CT
 366 scans. Also, the performance scores specifically the Dice coefficient is higher (about 3%) for DID-UNET
 367 compared to DD-UNET. In summary, the IDC model connected between the encoder-decoder structure,
 368 reduces loss of the original features but additionally expands the field of the segmented areas thereby
 369 improving the overall segmentation effect.

370

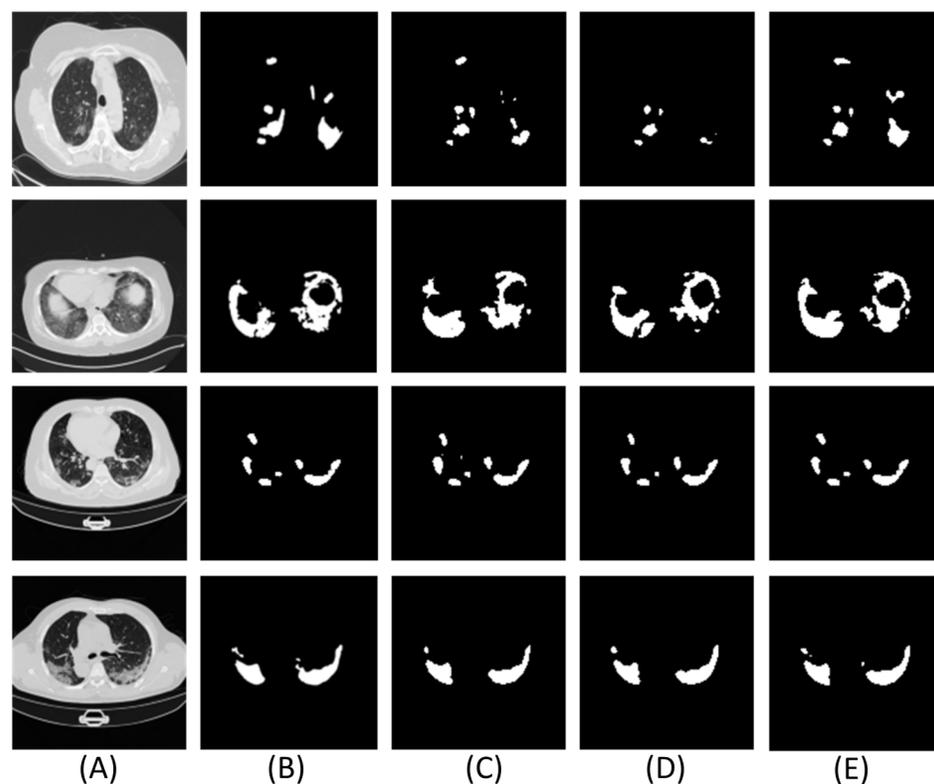

Figure 9. Experimental results of the improved dilation convolution and the traditional dilation convolution. Here (A) is the CT scan, (B) is the ground truth, (C)—(E) are the segment results from UNET, DD UNET and DID UNET, respectively.

Method	ACC	DC	S_{en}	S_p	P_c	AUC	F1	S_m	E_α	MAE
UNET	0.9696	0.7998	0.8052	0.9957	0.8247	0.9347	0.8154	0.8400	0.9390	0.0088
DD-UNET	0.9697	0.7757	0.7402	0.9971	0.8622	0.9214	0.7923	0.8401	0.9312	0.0094
DID-UNET	0.9700	0.8023	0.7987	0.9964	0.8425	0.9549	0.8241	0.8447	0.9374	0.0084

Table 4. The results of comparison indexes of the improved dilation convolution experiment and the traditional dilation convolution experiment.

371 3.4 Attention Gate

372 Although the improved dilation convolution improves the feature learning ability of the network, due to
 373 the loss of spatial information in the feature mapping at the end of the encoder structure, the network has
 374 difficulties in reducing false prediction for (a) small COVID-19 infected regions and (b) areas with blurry
 375 edges with poor contrast between the lesion and background. To solve this problem, we introduce the

376 attention gate (AG) model shown in Figure 10 mechanism into our model instead of simple cropping and
 377 copying. AG model computes the attention coefficient $\sigma \in [0, 1]$, based on equation (8):

$$\sigma = \varepsilon_2 \{ p_k [p_i (\varepsilon_1 (p_n \times n + p_m \times m + b_{m,n})) + b_{int}] + b_k \} \quad (8)$$

$$\varepsilon_2(x) = \frac{1}{1 + \exp(-x)} \quad (9)$$

378 where n and m represent the feature mapping of the AG module input from the decoder and encoder
 379 pipelines, respectively. And p_m, p_n, p_i, p_k are the convolution kernels of size 1×1 . $b_{m,n}, b_{int}, b_k$ represent
 380 the offset unit. ε_1 and ε_2 denote the RELU and sigmoid activation function respectively. Here ε_2 limits
 381 the range between 0 and 1.

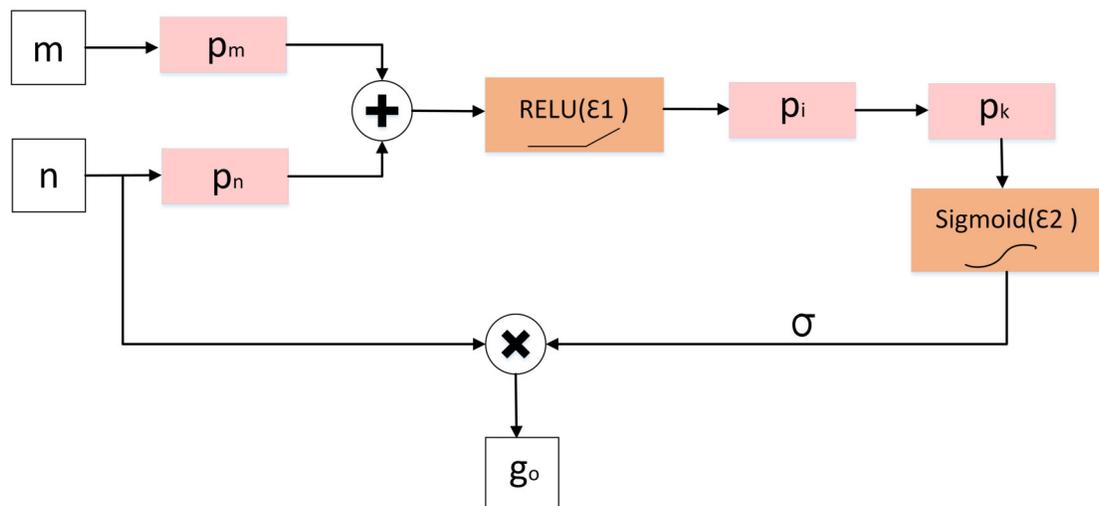

Figure 10. Diagram of Attention Gate(AG).

382 Finally, the attention coefficient σ is multiplied by the input feature map f_i to present the output g_o as
 383 shown in equation(10):

$$g_o = \sigma \times f_i \quad (10)$$

384 From Figure 11 and Table 5, results showed that the inclusion AG module improved the performance
 385 of the network (ADID-UNET), with segmentation accuracy of almost 97%. Therefore, by introducing the
 386 AG model, the network makes full use of the output feature information of encoder and decoder, which
 387 greatly reduces the probability of false prediction of small targets, and effectively improves the sensitivity
 388 and accuracy of the model.

389 4 EXPERIMENT RESULTS

390 4.1 COVID-19 segmentation dataset collection and processing

391 Organizing a COVID-19 segmentation dataset is time-consuming and hence there are not many CT
 392 scan segmentation datasets. At present, there was only one standard dataset namely the COVID-19
 393 segmentation dataset (Medseg.ai, 2020), which was composed of 100 axial CT scans from different
 394 COVID-19 patients. All CT scans were segmented by radiologists associated with the Italian Association
 395 of medicine and interventional radiology. Since the database was updated regularly, on April 13, 2020,
 396 another segmented CT scans dataset with segment labels from Radiopaedia was added. The whole
 397 datasets that contained both positive and negative slices (373 out of the total of 829 slices have been evalu-
 398 ated by a radiologist as positive and segmented), were selected for training and testing the proposed model.
 399

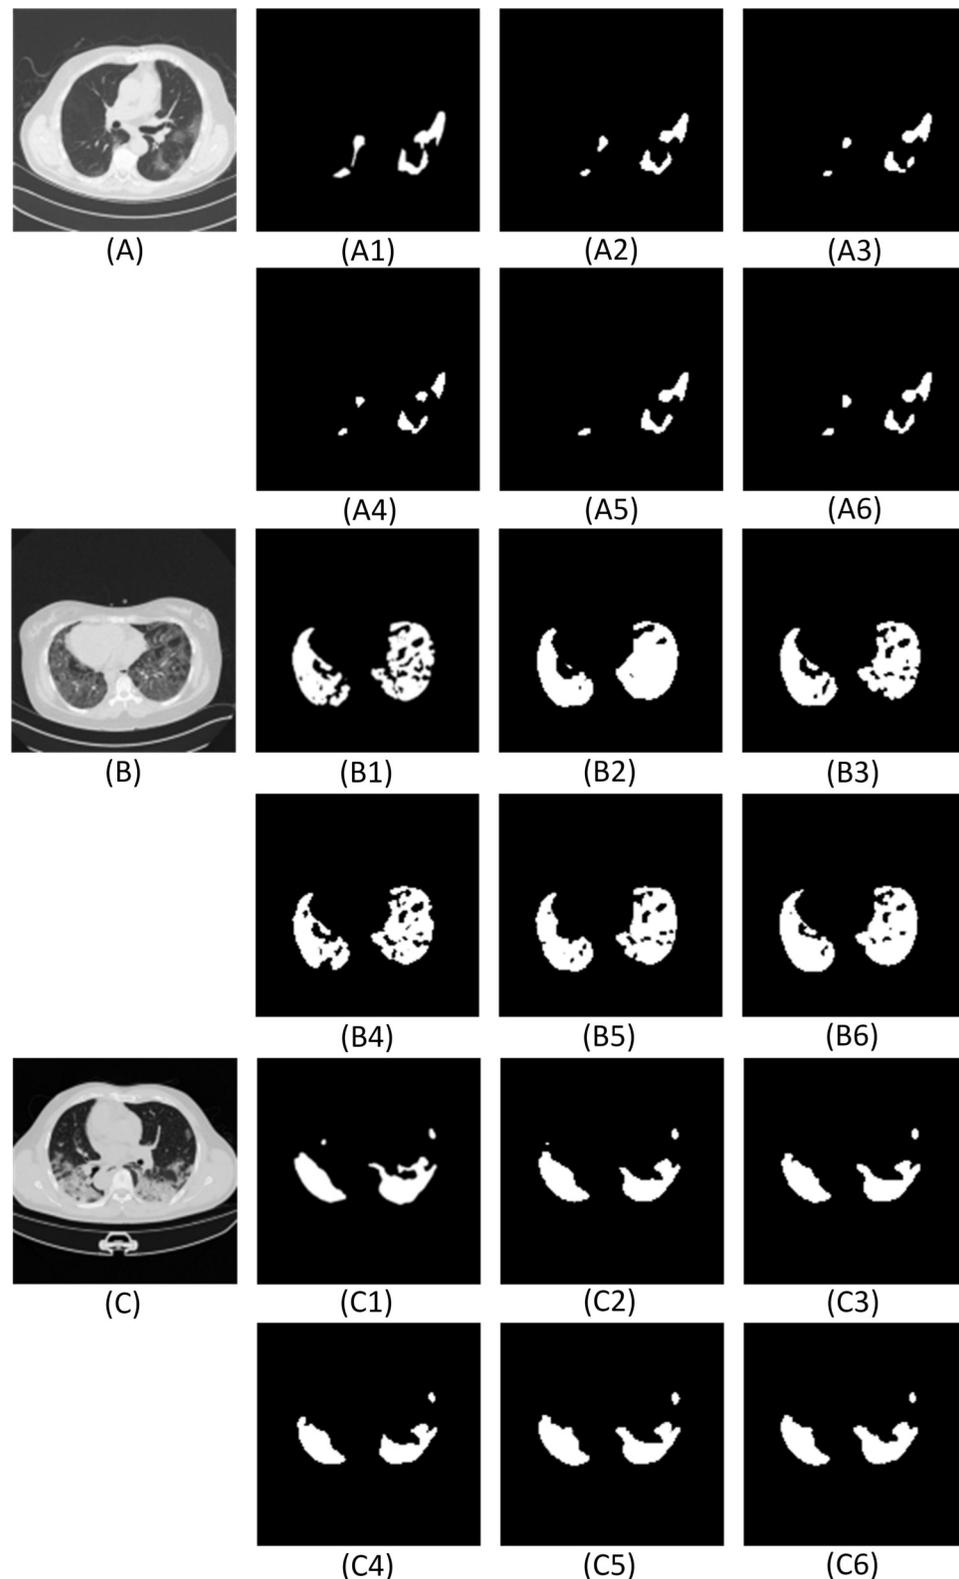

Figure 11. The qualitative results of comparative experiments with or without Attention Gate in the network. Here (A—C) illustrates the test images. (A1), (B1), (C1) are the ground truth. (A2)—(A6), (B2)—(B6), (C2)—(C6) are the segmentation results from UNET, AG-UNET, DA-UNET, IDA-UNET and ADID-UNET, respectively. AG-UNET—the addition of AG module to UNET, DA-UNET—adding two dense networks and AG module to the network without including the IDC module. IDA-UNET refers to adding IDC and AG modules to the UNET without adding dense networks, and ADID-UNET indicates that dense networks, IDC and AG module are added to the network.

Method	ACC	DC	S_{en}	S_p	P_c	AUC	F1	S_m	E_α	MAE
UNET	0.9696	0.7998	0.8052	0.9957	0.8247	0.9347	0.8154	0.8400	0.9390	0.0088
AG-UNET	0.9697	0.8020	0.8106	0.9962	0.8347	0.9571	0.8116	0.8511	0.9345	0.0087
DA-UNET	0.9698	0.7754	0.7400	0.9959	0.8470	0.9274	0.7930	0.8334	0.9104	0.0091
IDA-UNET	0.9698	0.7961	0.7834	0.9964	0.8469	0.9450	0.8126	0.8513	0.9437	0.0085
ADID-UNET	0.9701	0.8031	0.7973	0.9966	0.8476	0.9551	0.8200	0.8509	0.9449	0.0082

Table 5. The quantitative results of the comparison with or without the AG model experiment. AG-UNET– the addition of AG module to UNET, DA-UNET–adding two dense networks and AG module to the network without including the IDC module. IDA-UNET refers to adding IDC and AG modules to the UNET without adding dense networks, and ADID-UNET indicates that dense network, IDC and AG module are added to the network.

400 The dataset consists of 1838 images with annotated ground truth was randomly divided into 1318
 401 training samples, 320 validation samples, and 200 test samples. Since the number of training images is
 402 less, we expand the training dataset where we first merge the COVID-19 lung CT scans with the ground
 403 scene and then perform six affine transformations as mentioned in Krizhevsky et al. (2012). Later the
 404 transformed image is separated from the new background truth value and added to the training dataset as
 405 additional training images. Therefore, the 1318 images of the training dataset are expanded, and 9226
 406 images are obtained for training. Figure 12 illustrates the data expansion process.

407

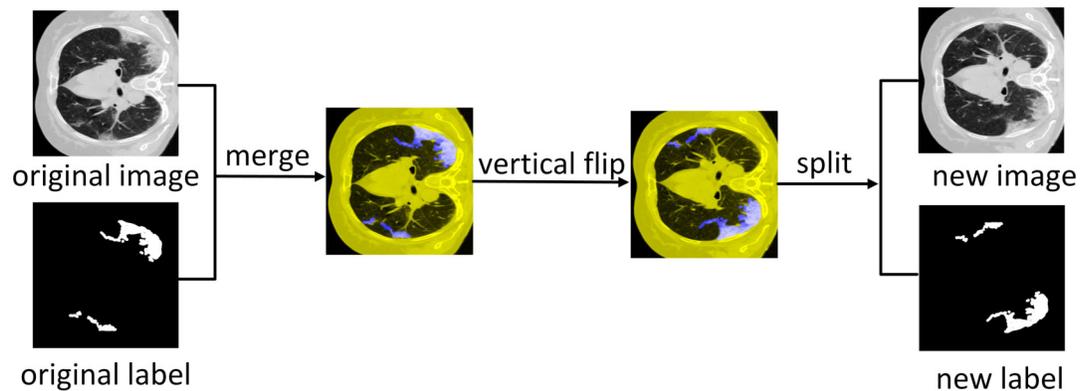

Figure 12. Data augmentation. Illustration of vertical flipping process showing the expansion of the training dataset.

408 4.2 Segmentation evaluation index

409 The commonly used evaluation indicators for segmentation such as accuracy (ACC), precision (P_c), Dice
 410 coefficient (DC), the area under the curve (AUC), sensitivity (S_{en}), specificity (S_p) and F1 score (F1) were
 411 used to evaluate the performance of the model. These performance indicators are calculated as follows:
 412 (1) For computing accuracy, precision, sensitivity, specificity, and F1 score we generate the confusion
 413 matrix where the definitions of true positive (TP), true negative (TN), false positive (FP), and false negative
 414 (FN) are shown in Table 6.

Category	Actual Lesion	Actual Non-Lesion
Predicted Lesion	True Position(TP)	False Position(FP)
Predicted Non-Lesion	False Negative(FN)	True Negative(TN)

Table 6. Definition of TP, FP, FN, TN.

415 1) **Accuracy (ACC)**: A ratio of the number of correctly predicted pixels to the total number of pixels in
416 the image.

$$\text{Accuracy(ACC)} = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

417 2) **Precision (P_c)**: A ratio of the number of correctly predicted lesion pixels to the total number of
418 predicted lesion pixels.

$$\text{Precision}(P_c) = \frac{TP}{TP + FP} \quad (12)$$

419 3) **Sensitivity (S_{en})**: A ratio of the number of correctly predicted lesion pixels to the total number of
420 actual lesion pixels.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \quad (13)$$

421 4) **F1 score (F1)**: A measure of balanced accuracy obtained from a combination of precision and sensitivity
422 results.

$$\text{F1score(F1)} = 2 \times \frac{P_c \times S_{en}}{P_c + S_{en}} \quad (14)$$

423 5) **Specificity (S_p)**: A ratio of the number of correctly predicted non-lesion pixels to the total number of
424 actual non-lesion pixels.

$$\text{Specificity}(S_p) = \frac{TN}{TN + FP} \quad (15)$$

425 6) **Dice coefficient (DC)**: Represents the similarity between the model segment output (Y) and the ground
426 truth (X). The higher the similarity between the lesion and the ground truth, the larger the Dice coefficient
427 and the better the segmentation effect. Dice coefficient is calculated as follows:

$$\text{Dice Coefficient(DC)} = \frac{2 \times (X \cap Y)}{X + Y} \quad (16)$$

428 Also, we use a Dice coefficient (Dice, 1945) loss (dice_loss) as the training loss of the model, the
429 calculation is as follows:

$$\text{Train Loss} = \text{Dice Coefficient Loss} = 1.0 - \frac{2 \times (X \cap Y)}{X + Y} \quad (17)$$

430 7) **The area under the curve (AUC)**: AUC is the area under the receiver operating characteristic (ROC)
431 curve. It represents the degree or the measure of separability and indicates the capability of the model in
432 distinguishing the classes. Higher the AUC better is the segmentation output and hence the model.

433 In addition to the above widely used indicators, we also introduce the Structural metric (S_m) (Fan
434 et al., 2017), Enhanced alignment metric (E_α) (Fan et al., 2018) and Mean Absolute Error (MAE) (Fan
435 et al., 2020; Elharrouss et al., 2020) to measure the segmentation similarity with respect to the ground
436 truth.

437 8) **Structural metric (S_m)**: Measures the structural similarity between the prediction map and ground
438 truth segmented mask, it is more in line with the human visual system than Dice coefficient.

$$S_m = (1 - \beta) \times S_{os}(S_{op}, S_{gt}) + \beta \times S_{or}(S_{op}, S_{gt}) \quad (18)$$

439 where S_{os} stands for target perception similarity, S_{or} stands for regional perceptual similarity, $\beta = 0.5$ is a
440 balance factor between S_{os} and S_{or} . And S_{op} stands for the final prediction result and S_{gt} represents the
441 ground truth.

442 9) **Enhance alignment metric (E_α)**: Evaluates the local and global similarity between two binary maps
443 computed based on equation (19):

$$E_\alpha = \frac{1}{w \times h} \sum_i^w \sum_j^h \alpha \times (S_{op}(i, j), S_{gt}(i, j)) \quad (19)$$

444 where w and h are the width and height of ground truth S_{gt} , (i, j) denotes the coordinates of each pixel in
445 S_{gt} . α represents the enhanced alignment matrix:

$$\alpha = \frac{2 \times (S_{gt} - \sqrt{S_{gt}}) \times (S_{op} - \sqrt{S_{op}})}{(S_{gt} - \sqrt{S_{gt}})^2 + (S_{op} - \sqrt{S_{op}})^2} \quad (20)$$

446 10) **Mean Absolute Error (MAE)**: Measures the pixel-wise difference between S_{op} and S_{gt} , defined as:

$$\text{MAE} = \frac{1}{w \times h} \sum_i^w \sum_j^h |S_{op}(i, j) - S_{gt}(i, j)| \quad (21)$$

4.3 Experimental details

The ADID-UNET proposed in this paper is implemented in Keras framework and is trained and tested by using the workstation with NVIDIA GPU P5000. During the training process, we set the learning rate as $l_r = 1 \times 10^{-3}$, and Adam optimizer was selected as the optimization technique. The 9226 training samples, 320 verification samples, and 200 test samples were resized to 128×128 and trained with a batch size of 32 for 300 epochs. Figure 13-14 shows the performance curves obtained for the proposed ADID-UNET during training, validation, and testing.

4.4 Segmentation results and discussion

(1) **Qualitative results:** To show the performance of the ADID-UNET model, we used 200 pairs of COVID-19 lung infection CT scans as test data, and the segmentation results are shown in Figure 15. From the analysis of Figure 15, it was found that the ADID-UNET model can accurately segment the COVID-19 lung infection areas from the CT scans, especially the smaller infected areas, and the segmentation result is very close to the ground truth. This illustrates the effectiveness of the proposed method for the segmentation of COVID-19 lung infection regions from CT scans.

Further, we also compare the proposed model with other state-of-art segmentation models. From the results (Figures 16 and 17 and Table 7), we can infer that the ADID-UNET model presents segmentation outputs closer to the ground truth. In contrast, the FCN8s network (Long et al., 2015) presents more under and over segmented regions. Further RAD-UNET (Zhuang et al., 2019a) presents comparable segmentation results but its effect is less pronounced for smaller segments. Analyzing the segmentation visual results from Figures 16 and 17, we can clearly find that the ADID-UNET model proposed in this paper can accurately segment the COVID-19 lung infection regions than other state-of-the-art model with results close to the ground truth, which proves the efficacy of the proposed ADID-UNET model.

470

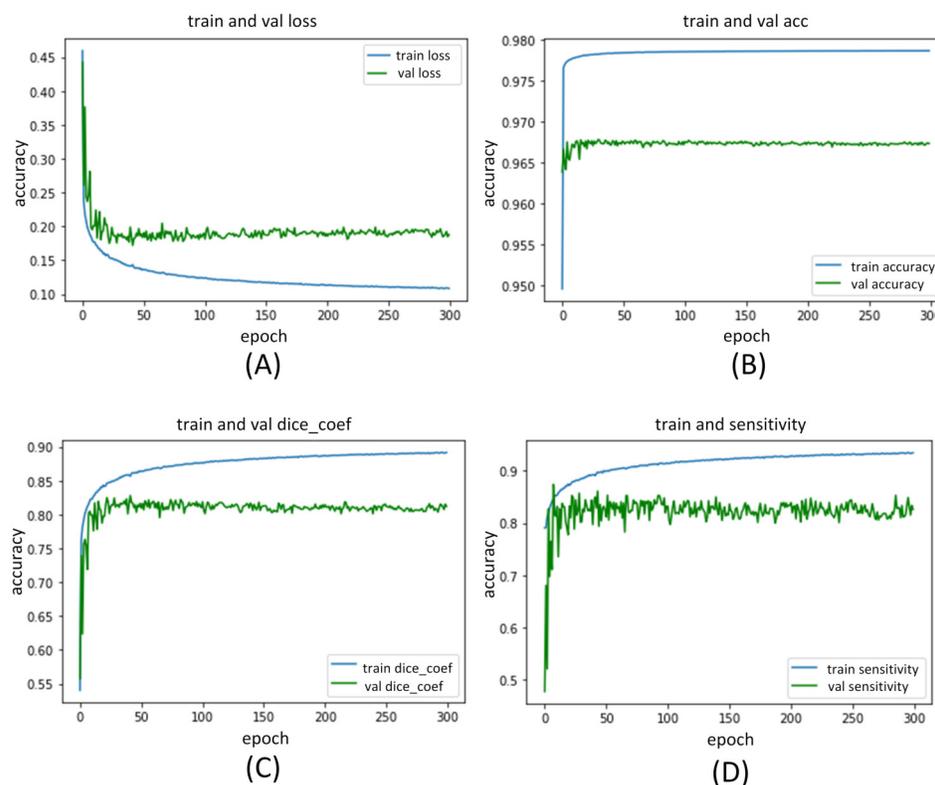

Figure 13. ADD-UNET training and validation performance index curve. (A-D) are the loss of training and validation, accuracy, Dice coefficient, and sensitivity performance curves, respectively.

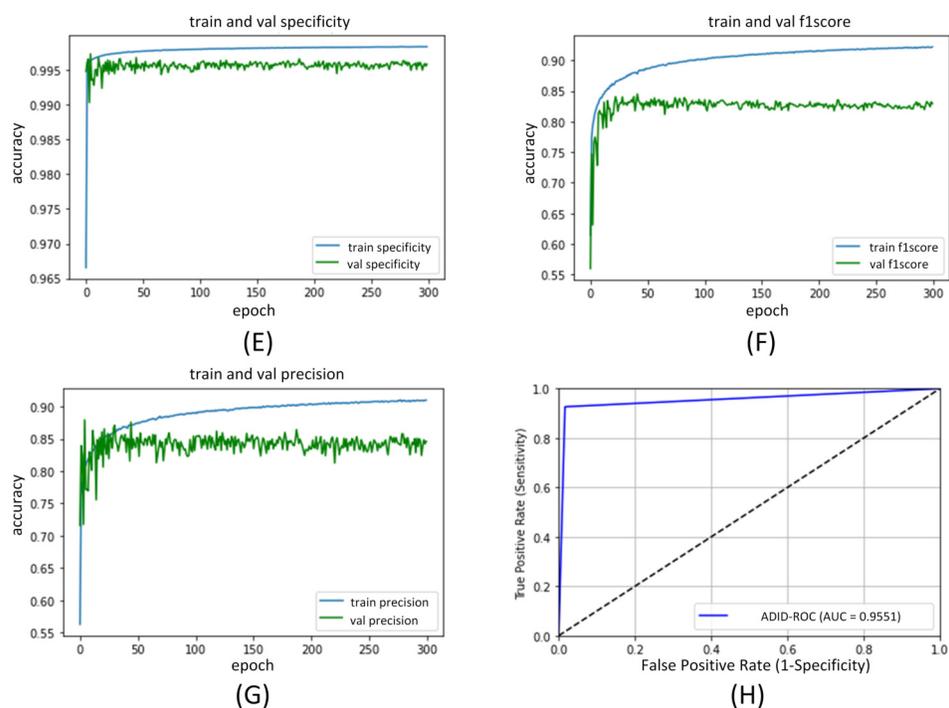

Figure 14. ADID-UNET training and validation performance index curve. (E-H) is the training and validation of the specificity, F1 score, precision, and AUC performance curves, respectively.

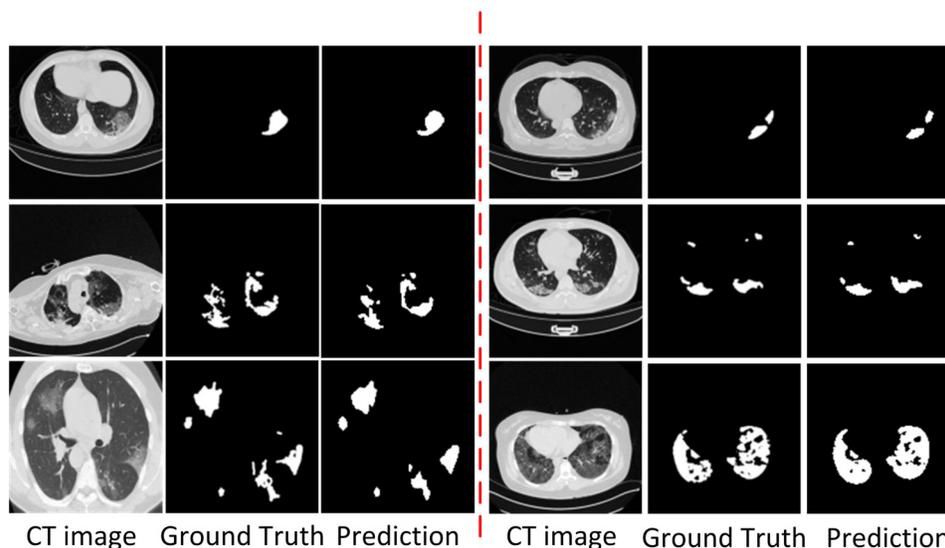

Figure 15. Visual comparison of the segmentation results of COVID-19 lung infection obtained from the proposed ADID-UNET.

471 (2) **Quantitative results:** Table 7, presents the performance scores for various indicators mentioned
 472 in Section 4. Here, for ADID-UNET the scores such as the Dice coefficient, precision, F1score, specificity
 473 and AUC are 80.31%, 84.76%, 82.00%, 99.66% and 95.51%, respectively. Further, most of the perfor-
 474 mance indexes are above 0.8 with the highest segmentation accuracy of 97.01%. The above results clearly
 475 indicates that the proposed model presents segmentation outputs closer to ground truth annotations.

476 (3) **Discussion:** The proposed model presents an improved version of the UNET model obtained by
 477 the inclusion of modules such as the dense network, IDC and the attention gates to the existing UNET
 478 (Ronneberger et al., 2015) structure. The effectiveness of these additions were experimentally verified

479 in Section 3. Further, to summarize the effectiveness of the addition of each module to the UNET
 480 architecture, Table 8 tabulates the improvement at each stage of the addition. From Table 8, it is found that
 481 adding additional components to the UNET (Ronneberger et al., 2015) structure can obviously improve
 482 the overall segmentation accuracy of the network. For example, with the inclusion of the dense networks
 483 (D-UNET), the metrics such as Dice coefficient (DC) and AUC reached 79.98% and 93.47%, respectively.

Method	ACC	DC	S_{en}	S_p	P_c	AUC	F1	S_m	E_α	MAE

Improvement of ADID-UNET	↑0.05%	↑0.33%	↓0.79%	↑0.09%	↑2.29%	↑2.04%	↑0.46%	↑1.09%	↑0.59%	↓0.06%

Table 8. The quantitative results showing percentages improvements of the model after adding additional components to UNET (Ronneberger et al., 2015) structure. D-UNET denotes dense networks with UNET structure, DID-UNET represents dense networks and improved dilation convolution to the structure of UNET, and ADID-UNET refers to proposed model with dense networks improved dilation convolution and attention gate modules to the UNET structure. ↑ indicates that the performance index is higher than that of UNET structure, ↓ indicates that the performance index is lower than that of UNET structure.

485 Further, the inclusion of the IDC improved the scores further (DID-UNET). Finally, the proposed
 486 model with dense network, IDC and the AG modules (namely ADID-UNET) presented the best perfor-
 487 mance scores and provided an improvement of 0.05%, 0.33%, 2.29%, 2.04% and 1.09% for metrics such
 488 as accuracy, DC, precision, AUC and structural metric respectively when compared to traditional UNET
 489 architecture.

490 Furthermore, from Figures 16 and 17, it is obvious that ADID-UNET performs better than other
 491 well-known segmentation models in terms of visualization. Specifically, ADID-UNET can segment
 492 relatively smaller infected regions which is of great significance for clinical accurate diagnosis of COVID-
 493 19 infection location. The use of (a) dense networks instead of traditional convolution and max-pooling
 494 function, (b) inclusion of improved dilation convolution module between the encoder-decoder pipeline and
 495 (c) the presence of attention gate network in the skip connections have presented accurate segmentation
 496 outputs for various types of COVID-19 infections (GGO and pulmonary consolidation). However, ADID-
 497 UNET still has room for improvement in terms of Dice coefficient and sensitivity and also computational
 498 costs which can be researched in future.

499

500 5 CONCLUSION

501 The paper proposes a new variant of UNET (Ronneberger et al., 2015) architecture to accurately segment
 502 the COVID-19 lung infections in CT scans. The model, ADID-UNET includes dense networks, improved
 503 dilation convolution, and attention gate, which has strong feature extraction and segment capabilities.
 504 The experimental results show that ADID-UNET is effective in segmenting small infection regions,
 505 with performance metrics such as accuracy, precision and F1 score of 97.01%, 84.76%, and 82.00%,
 506 respectively. The segmentation results of the ADID-UNET network can aid the clinicians in faster
 507 screening, quantification of the lesion areas and provide an overall improvement in the diagnosis of
 508 COVID-19 lung infection.

509 6 ACKNOWLEDGMENTS

510 We are very grateful to the Italian Society of medicine and interventional radiology, Radiopedia, and (Ma
 511 et al., 2020) for providing the COVID-19 CT scan segmentation database.

512 7 APPENDIX

513 We describe the abbreviations of this paper in detail, as shown in Table 9:

Abbreviation	Explanation
D-UNET	Inclusion of Dense networks to the UNET structure
AG-UNET	Inclusion of Attention gate module to the UNET structure
DA-UNET	Inclusion of both dense networks and attention gate module to the UNET structure
IDA-UNET	Inclusion of Improved dilation convolution and Attention Gate module to the UNET structure
DID-UNET	Inclusion of dense networks and improved dilation convolution to the UNET structure
ADID-UNET	Inclusion of dense networks, Improved dilation convolution and Attention Gate modules to the UNET structure

Table 9. An explanation of the acronyms that appears in this article.

514

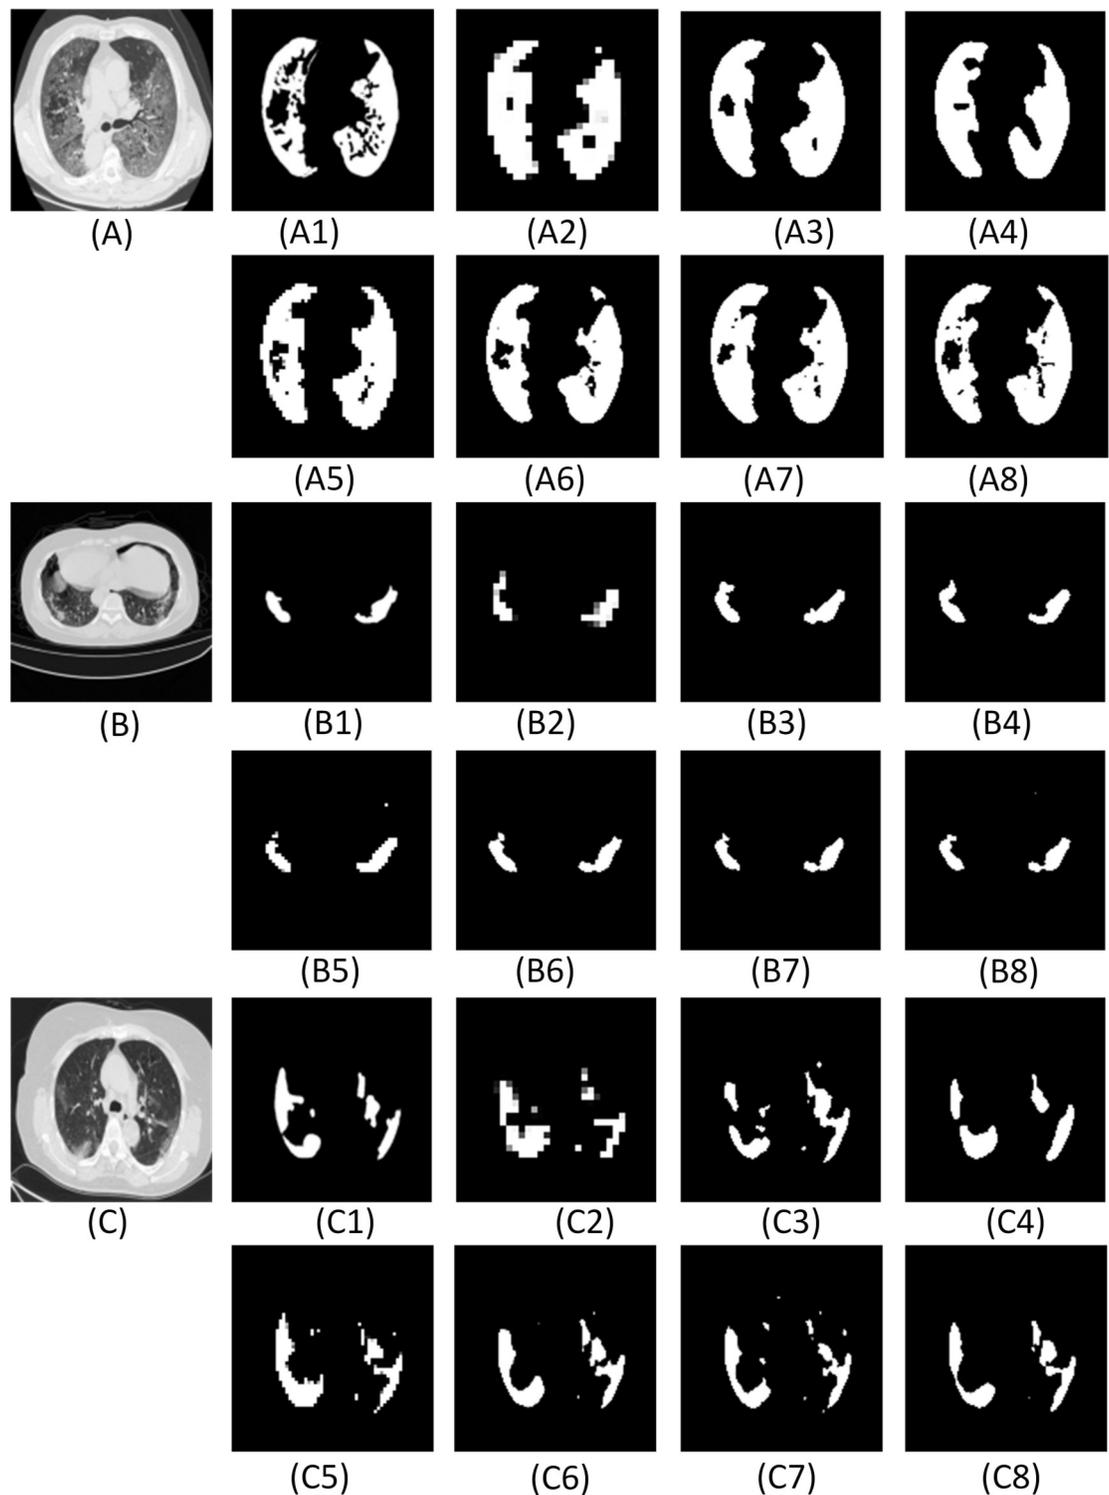

Figure 16. The visual comparison of the segmentation results of COVID-19 lung infection compared with other advanced models. Fig. 16 (A—C) illustrate the test images obtained from (Medseg.ai, 2020). Where (A1), (B1), (C1) are the ground truth, (A2)—(A8), (B2)—(B8), (C2)—(C8) are the segmentation results from FCN8s (Long et al., 2015), UNET (Ronneberger et al., 2015), SegNet (Badrinarayanan et al., 2017), Squeeze UNET (Iandola et al., 2016), Residual UNET (Alom et al., 2018), RAD UNET (Zhuang et al., 2019a), ADID-UNET, respectively.

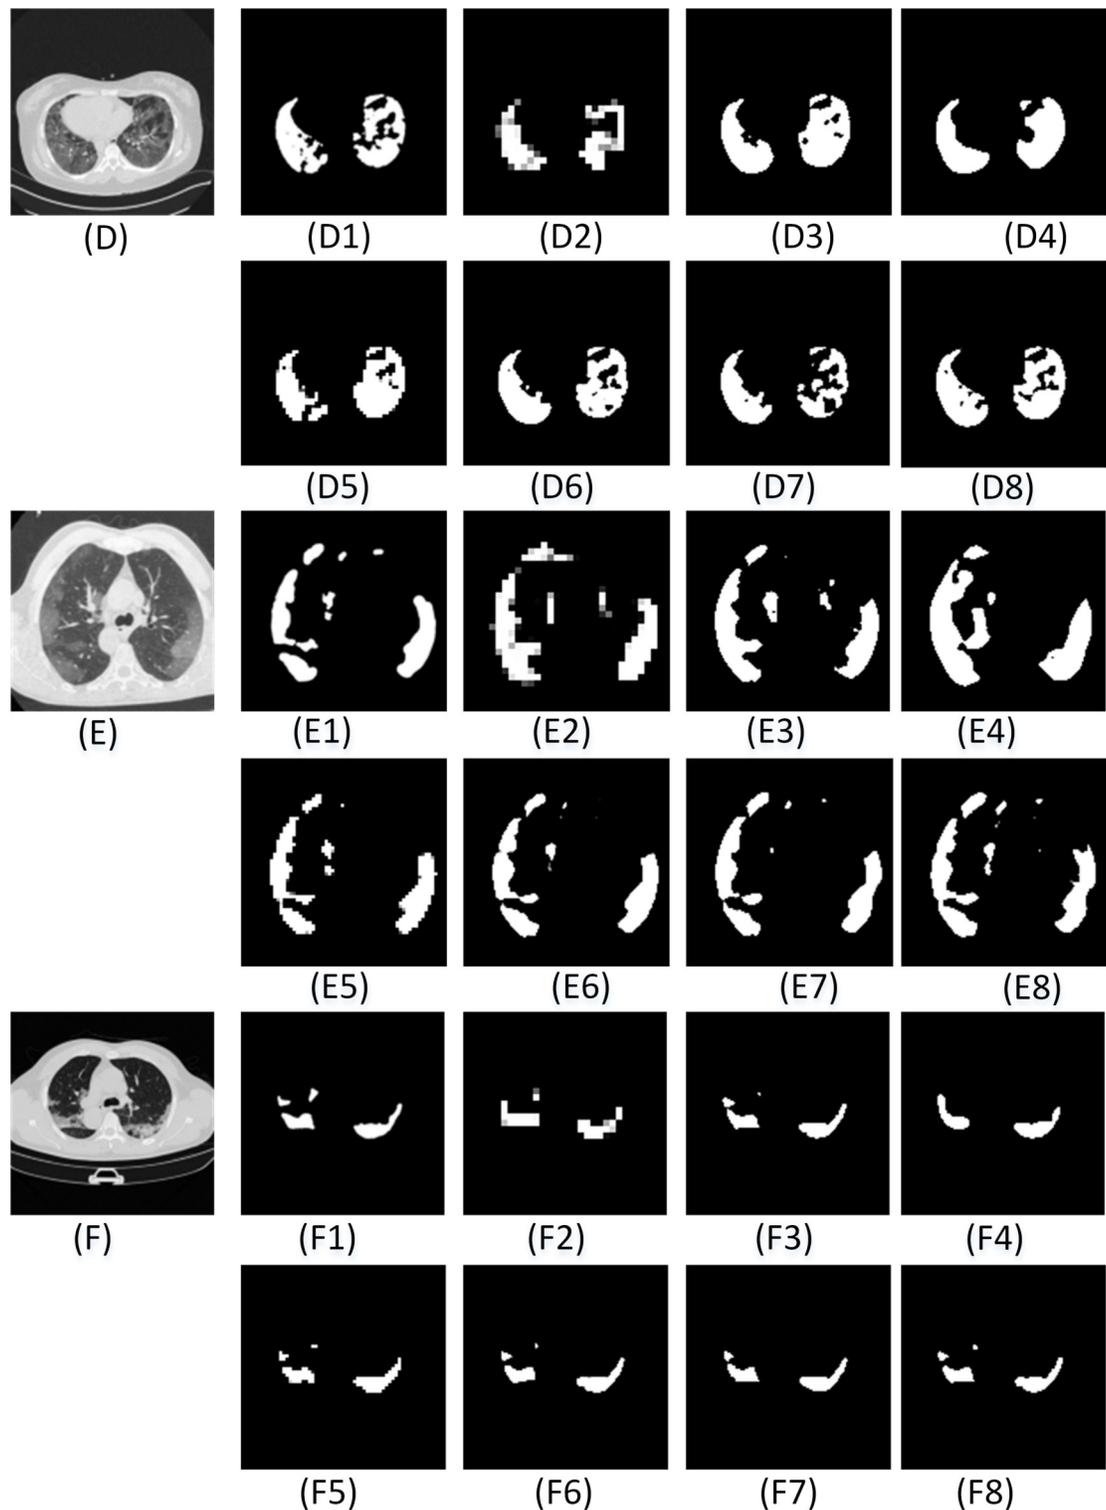

Figure 17. The visual comparison of the segmentation results of COVID-19 lung infection compared with other advanced models. Fig. 17 (D—F) illustrate the test images obtained from (Medseg.ai, 2020). Where (D1), (E1), (F1) are the ground truth, (D2)—(D8), (E2)—(E8), (F2)—(F8) are the segmentation results from FCN8s (Long et al., 2015), UNET (Ronneberger et al., 2015), Segnet (Badrinarayanan et al., 2017), Squeeze UNET (Iandola et al., 2016), Residual UNET (Alom et al., 2018), RAD UNET (Zhuang et al., 2019a), ADID-UNET, respectively.
