The internet movie database (IMDB) being one of the popular online databases for movies and personalities, provides a wide range of movie reviews from millions of users. This provides a diverse and large dataset to analyze users' sentiments about various personalities and movies. Despite being helpful to provide the critique of movies, the reviews on IMDB can not be read as a whole and requires automated tools to provide insights on the sentiments in such reviews. This study provides the implementation of various machine learning models to measure the polarity of the sentiments presented in user reviews on the IMDB website. For this purpose, the reviews are first preprocessed to remove redundant information and noise, and then various classification models like support vector machines (SVM), Naïve Bayes classifier, random forest, and gradient boosting classifiers are used to predict the sentiment of these reviews. The objective is to find the optimal process and approach to attain the highest accuracy with the best generalization. Various feature engineering approaches such as term frequency-inverse document frequency (TF-IDF), bag of words, global vectors for word representations, and Word2Vec are applied along with the hyperparameter tuning of the classification models to enhance the classification accuracy. Experimental results indicate that the SVM obtains the highest accuracy when used with TF-IDF features and achieves an accuracy of 89.55%. The sentiment classification accuracy of the models is affected due to the contradictions in the user sentiments in the reviews and assigned labels. For tackling this issue, TextBlob is used to assign a sentiment to the dataset containing reviews before it can be used for training. Experimental results on TextBlob assigned sentiments indicate that an accuracy of 92% can be obtained using the proposed model.

16 ABSTRACT

17 The internet movie database (IMDB) being one of the popular online databases for movies and personali-
18 ties, provides a wide range of movie reviews from millions of users. This provides a diverse and large
19 dataset to analyze users' sentiments about various personalities and movies. Despite being helpful to
20 provide the critique of movies, the reviews on IMDB can not be read as a whole and requires automated
21 tools to provide insights on the sentiments in such reviews. This study provides the implementation of
22 various machine learning models to measure the polarity of the sentiments presented in user reviews on
23 the IMDB website. For this purpose, the reviews are first preprocessed to remove redundant information
24 and noise, and then various classification models like support vector machines (SVM), Naïve Bayes
25 classifier, random forest, and gradient boosting classifiers are used to predict the sentiment of these
26 reviews. The objective is to find the optimal process and approach to attain the highest accuracy with the
27 best generalization. Various feature engineering approaches such as term frequency-inverse document
28 frequency (TF-IDF), bag of words, global vectors for word representations, and Word2Vec are applied
29 along with the hyperparameter tuning of the classification models to enhance the classification accuracy.
30 Experimental results indicate that the SVM obtains the highest accuracy when used with TF-IDF features
31 and achieves an accuracy of 89.55%. The sentiment classification accuracy of the models is affected due
32 to the contradictions in the user sentiments in the reviews and assigned labels. For tackling this issue,
33 TextBlob is used to assign a sentiment to the dataset containing reviews before it can be used for training.
34 Experimental results on TextBlob assigned sentiments indicate that an accuracy of 92% can be obtained
35 using the proposed model.

36 INTRODUCTION

37 Social media has become an integral part of human lives in recent times. People want to share their
38 opinions, ideas, comments, and daily life events on social media. In modern times, social media is used
39 for showcasing one's esteem and prestige by posting photos, text, and video clips, etc. The rise and wide
40 usage of social media platforms and microblogging websites provide the opportunity to share as you like
41 where people share their opinions on trending topics, politics, movie reviews, etc. Shared opinions on
42 social networking sites are generally known as short texts (ST) concerning the length of the posted text
43 (Sahu and Ahuja, 2016). ST has gained significant importance over traditional blogging because of its
44 simplicity and effectiveness to influence the crowd. These ST take the form of jargon and are even used by

search engines as queries. Apart from being inspiring, the ST contains users' sentiments about a specific personality, topic, or movie and can be leveraged to identify the popularity of the discussed item. The process of mining the sentiment from the texts is called sentiment analysis (SA) and has been regarded as a significant research area during the last few years (Hearst, 2003). Sentiments given on social media platforms like Twitter, Facebook, etc. can be used to analyze the perception of people about a personality, service, or product, as well as, used to predict the outcome of various social and political campaigns. Thus, SA helps to increase the popularity and followers of political leaders, as well as, other important personalities. Many large companies like Amazon, Apple, and Google use the reviews of their employees to analyze the response to various services and policies. In the business sector, companies use SA to derive new strategies based on customer feedback and reviews (Hand and Adams, 2014; Alpaydin, 2020).

Besides the social media platforms, several websites serve as a common platform for discussions about social events, sports, and movies, etc., and the internet movie database (IMDB) is one of the websites that offer a common interface to discuss movies and provide reviews. Reviews are short texts that generally express an opinion about movies or products. These reviews play a vital role in the success of movies or sales of the products (Agarwal and Mittal, 2016). People generally look into blogs, review sites like IMDB to know the movie cast, crew, reviews, and ratings of other people. Hence it is not only the word of mouth that brings the audience to the theaters, reviews also play a prominent role in the promotion of the movies. SA on movie reviews thus helps to perform opinion summarization by extracting and analyzing the sentiments expressed by the reviewers (Ikonomakis et al., 2005). Being said that the reviews contain valuable and very useful content, the new user can't read all the reviews and perceive the positive or negative sentiment. The use of machine learning approaches proves to ease this difficult task by automatically classifying the sentiments of these reviews. Sentiment classification involves three types of approaches including the supervised machine learning approach, using the semantic orientation of the text, and use of SentiWordNet based libraries (Singh et al., 2013a).

Despite being several approaches presented, several challenges remain unresolved to achieve the best possible accuracy for sentiment analysis. For example, a standard sequence for preprocessing steps is not defined and several variations are used which tend to show slightly different accuracy. Bag of words (BoW) is widely used for sentiment analysis, however, BoW loses word order information. Investigating the influence of other feature extraction approaches is of significant importance. Deep learning approaches tend to show better results than the traditional machine learning classifiers, but the extent of their better performance is not defined. This study uses various machine learning classifiers to perform sentiment analysis on the movie reviews and makes the following contributions

- This study proposes a methodology to perform the sentiment analysis on the movie reviews taken from the IMDB website. The proposed methodology involves preprocessing steps and various machine learning classifiers along with several feature extraction approaches.
- Both simple and ensemble classifiers are tested with the methodology including decision trees (DT), random forest (RF), gradient boosting classifier (GBC), and support vector machines (SVM). In addition, a deep learning model is used to evaluate its performance in comparison to traditional machine learning classifiers.
- Four feature extraction techniques are tested for their efficacy in sentiment classification. Feature extraction approaches include term frequency-inverse document frequency (TF-IDF), BoW, global vectors (GloVe) for word representations, and Word2Vec.
- Owing to the influence of the contradictions in users' sentiments in the reviews and assigned labels on the sentiment classification accuracy, in addition to the standard dataset, TextBlob annotated dataset is also used for experiments.
- The performance of the selected classifiers is analyzed using accuracy, precision, recall, and F1 score. Additionally, the results are compared with several state-of-the-art approaches to sentiment analysis.

The rest of this paper is organized as follows. Section 2 discusses a few research works which are closely related to the current study. The selected dataset, machine learning classifiers, and preprocessing procedure, and the proposed methodology are described in Section 3. Results are discussed in Section 4 and finally, Section 5 concludes the paper with possible directions for future research.

97 RELATED WORK

98 A large amount of generated data on social media platforms on Facebook, and Twitter, etc. are generating
99 new opportunities and challenges for the researchers to fetch useful and meaningful information to
100 thrive business communities and serve the public. As a result, multidimensional research efforts have
101 been performed for sentiment classification and analysis. Various machine learning and deep learning
102 approaches have been presented in the literature in this regard. Few research works which is related to
103 the current study are discussed here; we divide the research works into two categories: machine learning
104 approaches and deep learning approaches.

105 The use of machine learning algorithms has been accelerated in several domains including image
106 processing, object detection and natural language processing tasks, etc. (Ashraf et al., 2019a; Khalid et al.,
107 2020; Ashraf et al., 2019b). For example, The study (Hakak et al., 2021) uses a machine learning approach
108 for the fake new classification. The study proposes a feature selection technique and an ensemble classifier
109 using three machine learning classifiers including DT, RF, and extra tree classifier. The proposed model
110 achieves a good accuracy score on the 'Liar dataset' as compared to the ISOT dataset.

111 The authors implement several machine learning classification models for sentiment classification
112 of IMDB reviews into positive and negative sentiments in (Pang et al., 2002a). For this purpose, a
113 dataset containing 752 negative reviews and 1,301 positive reviews from the IMDB website is used. The
114 research aims at finding the suitable model with the highest F1 score and best generalization. Various
115 combinations of features and hyperparameters are used for training the classifiers for better accuracy.
116 K-fold cross-validation is used for evaluating the performance of the classifiers. Naive Bayes tend to
117 achieve higher accuracy of 89.2% than the SVM classifier which achieves 81.0% accuracy.

118 Similarly, the study (Singh et al., 2013a) conducts experimental work on performance evaluation of the
119 SentiWordNet approach for classification of movie reviews. The SentiWordNet approach is implemented
120 with different variations of linguistic features, scoring schemes, and aggregation thresholds. For evaluation,
121 two large datasets of movie reviews are used that contain the posts on movies about revolutionary changes
122 in Libya and Tunisia. The performance of the SentiWordNet approach is compared with two machine
123 learning approaches including NB and SVM for sentiment classification. The comparative performance
124 of the SentiWordNet and machine learning classifiers show that both NB and SVM perform better than all
125 the variations of SentiWordNet.

126 A hybrid method is proposed in (Singh et al., 2013b) where the features are extracted by using
127 both statistical and lexicon methods. In addition, various feature selection methods are applied such as
128 Chi-Square, correlation, information gain, and regularized locality preserving indexing (RLPI) for the
129 features extraction. It helps to map the higher dimension input space to the lower dimension input space.
130 Features from both methods are combined to make a new feature set with lower dimension input space.
131 SVM, NB, K- nearest neighbor (KNN), and maximum entropy (ME) classifiers are trained using the
132 IMDb movie review dataset. Results indicate that using hybrid features of TF and TF-IDF with Lexicon
133 features gives better results.

134 The authors propose an ensemble approach to improve the accuracy of sentiment analysis in (Minaee
135 et al., 2019). The ensemble model comprises convolutional neural network (CNN) and bidirectional
136 long short term memory (Bi-LSTM) networks and the experiments are performed on IMDB review and
137 Stanford sentiment treebank v2 (SST2) datasets. The ensemble is formed using the predicted scores of
138 the two models to make the final classification of the sentiment of the reviews. Results indicate that the
139 ensemble approach performs better than the state-of-the-art approaches and achieves an accuracy of 90%
140 to classify the sentiment from reviews.

141 The authors investigate the use of three deep learning classifiers including multilayer perceptron,
142 CNN, and LSTM for sentiment analysis in (Ali et al., 2019). Besides, experiments are also carried using a
143 hybrid model CNN-LSTM for sentiment classification, and the performance of these models is compared
144 with support vector machines and Naive Bayes. Multilayer Perceptron (MLP) is developed as a baseline
145 for other networks' results. LSTM network, CNN, and CNN-LSTM are applied on the IMDB dataset
146 consisting of 50,000 movies reviews. The word2vec is applied for word embedding. Results indicate
147 that higher accuracy of 89.2% can be achieved from the hybrid model CNN-LSTM. Individual classifiers
148 show a lower accuracy of 86.74%, 87.70%, and 86.64% for MLP, CNN, and LSTM, respectively.

149 Similarly, an ensemble classifier is proposed in (Yenter and Verma, 2017) which comprises CNN and
150 LSTM networks. The model aims at the word-level classification of the IMDB reviews. The output of
151 the CNN network is fed into an LSTM before being concatenated and sent to a fully connected layer to

produce a single final output. Various regularization techniques, network structures, and kernel sizes are used to generate five different models for classification. The designed models can predict the sentiment polarity of IMDB reviews with 89% or higher accuracy.

The study (Jain and Jain, 2021a) conducts experiments using the IMDB review dataset with deep learning models for sentiment classification. It uses a convolutional neural network (CNN) and long short-term memory (LSTM) with different activation functions. The highest accuracy of 0.883 is achieved with CNN using the ReLU activation function. Similarly, (Nafis and Awang, 2021) proposes a hybrid approach for IMDB review classification using TF-IDF and SVM. The approach called SVM-RFE uses important feature selection to train the SVM model. Feature selection helps in boosting the performance of SVM and increases the accuracy to 89.56% for IMDB reviews sentiment classification. The study (Giatsoglou et al., 2017) proposed an approach for sentiment analysis using a machine learning model. A hybrid feature vector is proposed by combining word2vec and BoW technique and experiments are performed using four datasets containing online user reviews in Greek and English language. In a similar fashion, (Mathapati et al., 2018) performs sentiment analysis on IMDB reviews using a deep learning approach. The study used a CNN and LSTM recurrent neural network to obtain significant accuracy on the IMDB reviews dataset.

The study (Jain and Jain, 2021b) uses a machine learning approach for IMDB reviews classification. The study performs preprocessing of data and proposes a feature selection technique using association rule mining (ARM). Results show that Naive Bayes (NB) outperforms all other used models by achieving a 0.784 accuracy score using the proposed features. The study (Qaisar, 2020) presents an approach using LSTM for IMDB review sentiment classification. LSTM achieves an 0.899 accuracy score on the IMDB dataset. Along the same lines, (Shaukat et al., 2020) performs experiments on the IMDB reviews dataset using a supervised machine learning approach. The study proposed neural network can achieve a 0.91 accuracy score.

From the above-discussed research works, it can be inferred that supervised machine and deep learning approaches show higher performance than lexicon-based approaches. Additionally, the accuracy offered by machine learning approaches requires further improvement, as shown in Table 1. This study focus on using several machine learning classifiers for this purpose, in addition to three feature extraction, approaches for enhanced classification performance. This study contributes to filling the literature gap which is accuracy and efficiency for IMDB review sentiment classification using state-of-the-art techniques.

MATERIALS AND METHODS

This section describes the dataset used for the experiments, machine learning classifiers selected for review classification, as well as, the proposed methodology and its working principles.

Data description

This study uses the 'IMDB Reviews' from Kaggle which contains users' reviews about movies (dat, 2018). The dataset has been largely used for text mining and consists of reviews of 50,000 movie reviews of which approximately 25,000 reviews belong to the positive and negative classes, respectively. Table 2 shows samples of reviews from both negative and positive classes.

TextBlob

TextBlob is a Python library that we used to annotate the dataset with new sentiments (Tex, 2020; Loria, 2018). TextBlob is used for labeling as the possibility of contradiction between the review text and label can not be ignored. TextBlob finds the polarity score for each word and then sums up these polarity scores to find the sentiment. TextBlob assigns a polarity score between -1 and 1. A polarity score greater than 0 shows the positive sentiment, a polarity score less than 0 shows a negative sentiment while a 0 score indicates that the sentiment is neutral. In the dataset used in this study, 23 neutral sentiments are found after applying TextBlob. Pertaining to the low number of neutral sentiments which can cause class imbalance, only negative and positive sentiments are used for experiments. Contradiction in TextBlob annotated label and original dataset label is shown in Table 3.

Table 1. Comprehensive summary of research works discussed in the related work.

Reference	Approach	Model	Aim

Feature Engineering Methods

Identification of useful features from the data is an important step for the better training of machine learning classifiers. The formation of secondary features from the original features enhances the efficiency of machine learning algorithms (Oghina et al., 2012; Mujahid et al., 2021). It is one of the critical factors to increase the accuracy of the learning algorithm and boost its performance. The desired accuracy can be

achieved by excluding the meaningless and redundant data. Less quantity of meaningful data is better than having a large quantity of meaningless data (Prabowo and Thelwall, 2009). So, feature engineering is the process of extracting meaningful features from raw data which helps in the learning process of algorithms and increases its efficiency and consistency (Lee et al., 2016).

210 **Bag of Words**

The BoW is simple to use and easy to implement for finding the features from raw text data (Rustam et al., 2021; Rupapara et al., 2021a). Many language modeling and text classification problems can be solved using the BoW features. In Python, the BoW is implemented using the CountVectorizer. BoW counts the occurrences of a word in the given text and formulates a feature vector of the whole text comprising of the counts of each unique word in the text. Each unique word is called 'token' and the feature vector is the matrix of these tokens (Liu et al., 2008). Despite being simple, BoW often surpasses many complicated feature engineering approaches in performance.

218 **Term Frequency-Inverse Document Frequency**

TF-IDF is another feature engineering method that is used to extract features from raw data. It is mostly deployed in areas like text analysis and music information retrieval (Yu, 2008). In this approach, weights are assigned to every term in a document based on term frequency and inverse document frequency (Neethu and Rajasree, 2013; Biau and Scornet, 2016). Terms having higher weights are supposed to be more important than terms having lower weights. The weight for each term is based on the equation 1.

$$W_{i,j} = TF_{i,d} \left(\frac{N}{D_{f,t}} \right) \quad (1)$$

where $TF_{i,d}$ is the number of occurrences of term t in document d , $D_{f,t}$ is the number of documents having the term t and N is the total number of documents in the dataset.

TF-IDF is a kind of scoring measurement approach which is widely used in summarization and information retrieval. TF calculates the frequency of a token and gives higher importance to more common tokens in a given document (Vishwanathan and Murty, 2002). On the other hand, IDF calculates the tokens which are rare in a corpus. In this way, if uncommon words appear in more than one document, they are considered meaningful and important. In a set of documents D , IDF weighs a token x using the equation 2.

$$IDF(x) = N/n(x) \quad (2)$$

Where $n(x)$ denotes frequency of x in D and $N/n(x)$ denotes the inverse frequency. TF-IDF is calculated using TF and IDF as shown in equation 3.

$$TF - IDF = TF \times IDF \quad (3)$$

TF-IDF is applied to calculate the weights of important terms and the final output of TF-IDF is in the form of a weight matrix. Values gradually increase to the count in TF-IDF but are balanced with the frequency of the word in dataset (Zhang et al., 2008).

237 **Word2Vec**

Word2Vec is one of the widely used NLP techniques for feature extraction in text mining that transforms text words into vectors (Wang et al., 2016). Given a corpus of text, Word2Vec uses a neural network model for learning word associations. Each unique word has an associated list of numbers called 'vector'. The cosine similarity of the vectors represents the semantic similarity between the words that are represented by vectors.

243 **GloVe**

GloVe from Global Vectors is an unsupervised model used to obtain words' vector representation (Bhoir et al., 2017). The vector representation is obtained by mapping the words in a space such that the distance between the words represents the semantic similarity. Developed at Stanford, GloVe can determine the similarity between words and arrange them in the vectors. The output matrix by the GloVe gives vector space of word with linear substructure.

249 **Supervised machine learning Models**

250 Several machine learning classifiers have been selected for evaluating the classification performs in this
251 study. A brief description of each of these classifiers is provided in the following sections.

252 **Random Forest**

253 Rf is based on combining multiple decision trees on various subsamples of the dataset to improve
254 classification accuracy. These subsamples are the combination of randomly selected features which are
255 the size of the original dataset to form a bootstrap dataset. The average of predictions from these models
256 is used to obtain a model with low variance. Information gain ratio and Gini index are the most frequently
257 used feature selection parameters to measure the impurity of feature (Agarwal et al., 2011).

$$\sum_{j \neq i} \left(\frac{f(C_i, T)}{|T|} \right) \left(\frac{f(C_j, T)}{|T|} \right) \quad (4)$$

258 where $\frac{f(C_i, T)}{|T|}$ indicates the probability of being a member of class C_i .

259 The decision trees are not pruned upon traversing each new training data set. The user can define
260 the number of features and number of trees on each node and set the values of other hyperparameters to
261 increase the classification accuracy (Biau and Scornet, 2016).

262 **Gradient Boosting Classifier**

263 GBC is an ensemble classifier used for classification tasks with enhanced accuracy based on boosting
264 (Ayyadevara, 2018). It combines many weak learners sequentially to reduce the error gradually. This
265 study uses the GBC with decision tree as a weak learner. GBC performance depends on the loss function
266 and mostly the logarithmic loss function is used for classification. In addition, weak learners and adaptive
267 components are important parameters of GBC. The hyperparameters setting of GBC used in this study is
268 shown in Table 4. GBC is used with 300 n_estimators indicating that 300 weak learners (decision trees)
269 are combined under boosting method and each tree is restricted to 300 max_depth. The learning_rate is set
270 to 0.2 which helps to reduce model overfitting (Rustam et al., 2020).

271 **Decision Tree**

272 DT is one of the most commonly used models for classification and prediction problems. DT is a simple
273 and powerful tool to understand data features and infer decisions. The decision trees are constructed by
274 repeatedly dividing the data according to split criteria. There are three types of nodes in a decision tree:
275 root, internal, and leaf. The root node has no incoming but zero or more outgoing edges, the internal node
276 has exactly one incoming but two or more outgoing edges while the leaf node has one incoming while no
277 outgoing edge (Bakshi et al., 2016; Tan et al., 2006). Nodes and edges represent features and decisions of
278 a decision tree, respectively. A decision tree can be binary or non-binary depending upon the leaves of a
279 node. The gain ratio is one of the commonly used split criteria for DT.

$$\text{Gain ratio} = \frac{\Delta_{info}}{\text{Split Info}} \quad (5)$$

280 where split info is defined as in equation 6.

$$\text{Split Info} = - \sum_{i=1}^k P(v_i) \log_2 P(v_i) \quad (6)$$

281 where k indicates the total number of splits for DT which is hyperparameter tuned for different
282 datasets to elevate the performance. DT is non-parametric, computationally inexpensive, and shows better
283 performance even when the data have redundant attributes.

284 **Support Vector Machine**

285 Originally proposed by Cortes and Vapnik in 1995 for binary classification, SVM is expanded for
286 multi-class classification (Cortes and Vapnik, 1995). SVM is a widely used approach for non-linear
287 classification, regression, and outlier detection (Bennett and Campbell, 2000). SVM has the additional

288 advantage of examining the relationship theoretically and performs distinctive classification than many
 289 complex approaches like neural networks (Agarwal and Mittal, 2016). SVM separates the classes
 290 by distinguishing the optimal isolating lines called hyperplane by maximizing the distance between
 291 the classes' nearest points (Neethu and Rajasree, 2013). Different kernels can be used with SVM to
 292 accomplish better performance such as radial, polynomial, neural, and linear (Guzman and Maalej, 2014).
 293 SVM is preferred for several reasons including the lack of local minimal, structural risk minimization
 294 principle, and developing more common classification ability (Visa et al., 2011; Vishwanathan and Murty,
 295 2002).

296 For optimizing the performance of the machine learning models used in this study, several hyperpa-
 297 rameters have been fine-tuned according to experience from the literature on text classification tasks. A
 298 list of the parameters and corresponding values used for experiments in this study is provided in Table 4.

Table 4. Hyperparameters used for optimizing the performance of models.

Model	Hyperparameters	Values range used for tuning
RF	n_estimators=300, random_state=50, max_depth=300	n_estimators = {50 to 500}, random_state = {2 to 60}, max_depth = {50 to 500}
SVM	kernel= 'linear' , C=3.0, random_state=50	kernel= { 'linear', 'poly', 'sigmoid' } , C={1.0 to 5.0}, random_state={2 to 60}
DT	random_state=50, max_depth=300	random_state = {2 to 60}, max_depth = {50 to 500}
GBC	n_estimators=300, random_state=50, max_depth=300, learning_rate=0.2	n_estimators = {50 to 500}, random_state = {2 to 60}, max_depth = {50 to 500}, learn- ing_rate = {0.1 to 0.8}

299 Proposed methodology

300 With the growing production of movies over the last two decades, a large number of opinions and reviews
 301 are posted on various social media platforms and websites. Such reviews are texts that show explicit
 302 opinions about a film or product. These opinions play an important part in the success of film or sales
 303 of the products (Agarwal and Mittal, 2016). People search blogs, and evaluation sites like IMDB to get
 304 the likes and dislikes of other people about films, the cast, and team, etc. but it is very difficult to read
 305 every review and comment. Evaluation of these sentiments becomes beneficial to assisting people in
 306 this task. Sentiments expressed in such reviews are important regarding the evaluation of the movies
 307 and their crew. Automatic sentiment analysis with higher accuracy is extremely important in this regard
 308 and this study follows the same direction and proposes an approach to perform the sentiment analysis of
 309 movie reviews. In addition, since the contradictions in the expressed sentiments in movie reviews and
 310 their assigned labels can not be ignored, this study additionally uses TextBlob to determine the sentiments.
 311 Two sets of experiments are performed using the standard dataset and TextBlob annotated dataset to fill in
 312 the research gap as previous studies do not consider the contradictions in the sentiments and assigned
 313 labels. Figure 1 shows the flow of the steps carried out for sentiment classification.

314 As a first step, the reviews are preprocessed using a sequence of operations. Preprocessing is critical
 315 to boosting the training of the classifiers and enhancing their performance. The purpose of preprocessing
 316 is to clean the data by removing unnecessary, meaningless, and redundant text from reviews. For this
 317 purpose, the six steps are carried sequentially, as shown in Figure 2.

318 Punctuation is removed from IMDB text reviews because punctuation does not add any value to
 319 text analysis (Guzman and Maalej, 2014). Sentences are more readable for humans due to punctuation,
 320 however, it is difficult for a machine to distinguish punctuation from other characters. Punctuation
 321 distorts a model's efficiency to distinguish between entropy, punctuation, and other characters (Rupapara
 322 et al., 2021b; Liu et al., 2008). So, punctuation is removed from the text in pre-processing to reduce
 323 the complexity of the feature space. Table 5 shows the text of a sample review, before and after the
 324 punctuation has been removed.

325 Once the punctuation is removed, the next step is to find numerical values and remove them as they
 326 are not valuable for text analysis. Numerical values are used in the reviews as an alternative to various
 327 English words to reduce the length of reviews and ease of writing the review. For example, 2 is used
 328 for 'to' and numerical values are used instead of counting like 1 instead of 'one'. Such numerals are

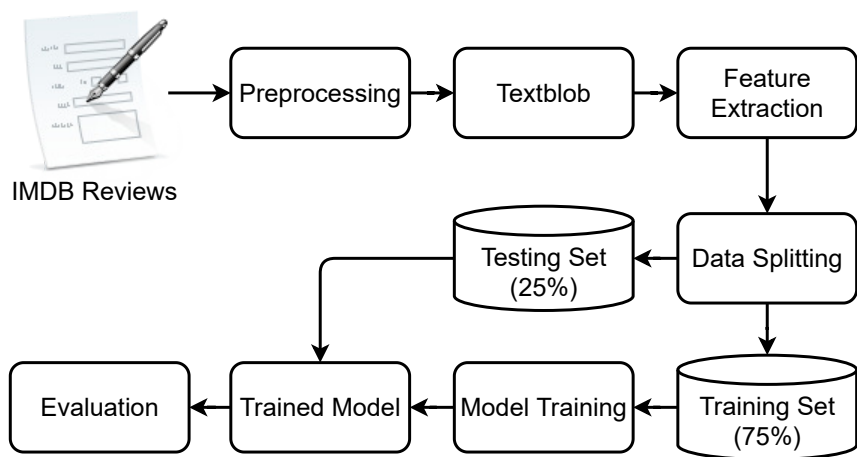

Figure 1. The work flow of proposed methodology for movie review classification.

Figure 2. Preprocessing steps for movies review dataset.

Table 5. Text from sample review before and after punctuation removal.

Before puncutation removal	After punctuation removal
@Gwyneth Paltrow is absolutely... !!!great in this movie. I own this movie. This is number 1 movie. . . I didn't like by choice, I do. I wish "that '70s show" would come back on tel.	Gwyneth Paltrow is absolutely great in this movie I own this movie This is number 1 movie I didnt like by choice I do I wish that 70s show would come back on tel

convenient for humans to interpret, yet offer no help in the training of machine learning classifiers. Table 6 shows text from sample reviews after the numeric values are removed.

Table 6. Sample text from movie reviews after removing numeric values.

Input Data	After Numeric Removal
Gwyneth Paltrow is absolutely great in this movie. I own this movie This is number 1 movie I didnt like by choice I do. I wish that 70s show would come back on tel.	Gwyneth Paltrow is absolutely great in this movie I own this movie This is number movie I didnt like by choice I do I wish that s show would come back on tel

In the subsequent step of numbers removal, all capital letters are converted to lower form. Machine learning classifiers can not distinguish between lower and upper case letters and consider them as different letters. For example, 'Health', and 'health' are considered as two separate words if conversion is not performed from uppercase to lowercase. It may reduce the significance of most occurred terms and degrade the performance (Liu et al., 2010). It increases the complexity of the feature space and reduces the performance of classifiers. So, converting the upper case letters to lower form helps in increasing the training efficiency of the classifiers. Table 7 shows the text after the case is changed for the reviews. Stemming is an important step in pre-processing because eliminating affixes from words and changing them into their root form is very helpful to enhance the efficiency of a model (Goel et al., 2016). For

Table 7. Sample output of the review text after changing the case of review text.

Input Data	After Case Lowering
Gwyneth Paltrow is absolutely great in this movie. I own this movie This is number movie I didnt like by choice I do. I wish that s show would come back on tel.	gwyneth paltrow is absolutely great in this movie i own this movie this is number movie i didnt like by choice i do i wish that s show would come back on tel

example, 'help', 'helped', and 'helping' are altered forms of 'help', however, machine learning classifiers consider them as two different words (Singh et al., 2013b). Stemming changes these different forms of words into their root form. Stemming is implemented using the PorterStemmer library of Python (Pang et al., 2002b). Table 8 shows the sample text of review before and after stemming.

Table 8. Text from sample review before and after stemming.

Input Data	After Stemming
gwyneth Paltrow is absolutely great in this movie. i own this movie this is number movie i didnt like by choice I do. i wish that s show would come back on tel.	gwyneth paltrow is absolute great in this movie i own this movie this is number movie i didnt like by choice i do i wish that s show would come back on tel

The last step in the preprocessing phase is the removal of stop words. Stop words have no importance concerning the training of the classifiers. Instead, they increase the feature vector size and reduce the performance. So they must be removed to decrease the complexity of feature space and boost the training of classifiers. Table 9 shows the text of the sample review after the stopwords have been removed.

Table 9. Sample reviews before and after the stop words removal.

Input Data	After Stopwords Removal
gwyneth Paltrow is absolutely great in this movie. i own this movie this is number movie i didnt like by choice I do. i wish that s show would come back on tel.	gwyneth paltrow absolute great movie own movie number movie didnt like choice do wish show would come back tel

After the preprocessing is complete, feature extraction takes place where BoW, TF-IDF, and GloVe are used. Feature space for the sample reviews is given in Tables 10 and 11 for BoW and TF-IDF features, respectively. Experiments are performed with the standard dataset, as well as, the TextBlob annotated dataset to analyze the performance of the machine learning and proposed models.

The data are split into training and testing sets in a 75 to 25 ratio. Machine learning classifiers are trained on the training set while the test set is used to evaluate the performance of the trained models. For evaluating the performance, standard well-known parameters are used such as accuracy, precision, recall, and F1 score.

Evaluation Parameters

Performance evaluation of the classifiers requires evaluation metrics for which accuracy, precision, recall, and F1 score are selected concerning their wide use. The introduction of the confusion matrix is necessary to define the mathematical formulas for these evaluation metrics. The confusion matrix as shown in Figure 3 can be considered as an error matrix that indicates four quantities. The confusion matrix shows true positive (TP), false positive (FP), true negative (TN), and false-negative (FN). Each row of the matrix represents the actual labels while each column represents predicted labels (Landy and Szalay, 1993).

No.	movie	number	own	paltrow	show	tel	wish	would	
1	0.355432	0.000000	0.000000	0.467351	0.000000	0.000000	0.000000	0.000000	
2	0.527533	0.346821	0.346821	0.000000	0.000000	0.000000	0.000000	0.000000	
3	0.000000	0.000000	0.000000	0.000000	0.408248	0.408248	0.408248	0.408248	

TP indicates that the classifier predicted the review as positive and the original label is also positive. A review is TN if it belongs to the negative class and the real outcome is also negative. In the FP case, the review is predicted as positive, but the original label is negative. Similarly, a review is called FN if it belongs to the positive class but the classifier predicted it as negative (Rokach and Maimon, 2005).

Accuracy is a widely used evaluation metrics and indicates the ratio of true predictions to the total predictions. It has a maximum value of 1 for 100 percent correct prediction and the lowest value of 0 for 0 percent prediction. Accuracy can be defined as

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (7)$$

Precision focuses on the accuracy of predicting the positive cases. It shows what proportion of the positively predicted cases is originally positive. It is defined as

$$Precision = \frac{TP}{TP + FP} \quad (8)$$

Recall calculates the ratio of correct positive cases to the total positive cases. To get the ratio, the total number of TP is divided by the sum of TP and FN as follows

$$Recall = \frac{TP}{TP + FN} \quad (9)$$

F1 score is considered an important parameter to evaluate the performance of a classifier and has been regarded as more important than precision and recall. It defines how precise and robust is the classifier by incorporating precision and recall (Bruce et al., 2002). F1 score value varies between 0 and 1 where 1 shows the perfect performance of the classifier. F1 score is defined as

$$F1Score = 2 \times \frac{precision \times recall}{precision + recall} \quad (10)$$

		Predicted Labels	
		Negative (0)	Positive (1)
Actual Labels	Negative (0)	True Negative(TN)	False Positive (FP)
	Positive (1)	False Negative(FN)	True Positive (TP)

Figure 3. Confusion matrix.

RESULTS AND DISCUSSION

This study uses four machine learning classifiers to classify movie reviews into positive and negative reviews, such as DT, SVM, RF, and GBC. Four feature extraction approaches are utilized including TF-IDF, BoW, Word2Vec, and GloVe on the selected dataset to extract the features. Results for these feature extraction approaches are discussed separately. Similarly, the influence of TextBlob annotated data on the classification accuracy is analyzed. The contradictions in the sentiments expressed in the reviewers and the assigned sentiments cannot be ignored, so TextBlob is used to annotate the labels. Several experiments are performed using the standard, as well as, the TextBlob annotated dataset.

Results using BoW Features

Table 12 shows the classification accuracy of the machine learning classifiers when BoW features to train and test the classifiers. Results indicate that SVM can achieve an accuracy of 0.87 with BoW features. Overall, the performance of all the classifiers is good except for DT whose accuracy is 0.72.

Table 12. Accuracy of the selected models with BoW features.

Classifier	Accuracy
DT	0.72
RF	0.86
GBC	0.85
SVM	0.87

Performance of the classifiers is given in Table 13 in terms of precision, recall, and F1 score. The F1 score indicates that its value is the same with both positive and negative classes for all the classifiers, except for GBC who has F1 scores of 0.86 and 0.85 for positive and negative classes, respectively. Precision values are slightly different for positive and negative classes; for example, SVM has a precision of 0.88 and 0.90 for positive and negative classes. Similarly, although precision, recall, and F1 score of DT are the lowest but the values for positive and negative classes are almost the same. An equal number of the training samples in the dataset makes a good fit for the classifiers, and their accuracy and F1 scores are in agreement.

Table 13. Performance evaluation metrics using BoW features.

Model	Precision			Recall			F1 score		
	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.71	0.72	0.72	0.72	0.71	0.72	0.72	0.72	0.72
RF	0.85	0.87	0.86	0.88	0.84	0.86	0.86	0.86	0.86
GBC	0.83	0.87	0.85	0.88	0.82	0.85	0.86	0.85	0.85
SVM	0.86	0.88	0.87	0.88	0.86	0.87	0.87	0.87	0.87

Results using TF-IDF Features

Table 14 contains the accuracy results for the classifiers using the TF-IDF features. It shows that the performance of the SVM has been elevated with an accuracy of 0.89 which is 2.29% higher than that of using BoW features. Unlike BoW which counts only the frequency of terms, TF-IDF also records the importance of terms by assigning higher weights to rare terms. So, the performance is improved when TF-IDF features are used as compared to BoW features.

Table 14. Accuracy of models with TF-IDF features.

Classifier	Accuracy
DT	0.71
RF	0.86
GBC	0.86
SVM	0.89

Results for precision, recall, and F1 score are given in Table 15. Experimental results indicate that the F1 score is the same for positive and negative classes for all classifiers which indicates the good fit of the models on the training data. On the other hand, precision for positive and negative classes is slightly different. For example, GBS has a precision of 0.84 and 0.87 while SVM has a precision of 0.88 and 0.90 for positive and negative classes, respectively.

Table 15. Performance evaluation metrics using TF-IDF features.

Model	Precision			Recall			F1 score		
	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.72	0.71	0.71	0.70	0.72	0.71	0.71	0.71	0.71
RF	0.86	0.86	0.86	0.86	0.85	0.86	0.86	0.86	0.86
GBC	0.84	0.87	0.86	0.88	0.83	0.86	0.86	0.85	0.86
SVM	0.88	0.90	0.89	0.90	0.88	0.89	0.89	0.89	0.89

SVM performs better for text classification than other supervised learning models, especially in the case of large datasets as this algorithm is derived from the theory of structural risk minimization (Mouthami et al., 2013).

Classifiers Results using GloVe Features

Experimental results using GloVe features are shown in Table 16 for the selected classifiers. Results suggest that the performance of all the classifiers has been degraded when trained and tested on GloVe features. GloVe features are based on the global word-to-word co-occurrence and count the co-occurred terms from the entire corpus. GloVe model is traditionally used with deep learning models where it helps to better recognize the relationships between the given samples of the dataset. In machine learning models, its performance is poor than that of TF-IDF features (Dessi et al., 2020). SVM and RF outperform other models using GloVe features.

Table 16. Performance of classifiers using GloVe features.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.65	0.64	0.65	0.65	0.64	0.65	0.65	0.65	0.65	0.65
RF	0.74	0.75	0.74	0.74	0.72	0.77	0.74	0.73	0.75	0.74
GBC	0.65	0.65	0.65	0.65	0.65	0.66	0.65	0.65	0.65	0.65
SVM	0.75	0.75	0.75	0.75	0.75	0.75	0.75	0.75	0.75	0.75

Results using Word2Vec Features

Performance evaluation metrics for all the classifiers using the Word2Vec features are given in Table 17. Results indicate that the performance of the classifiers is somehow better when trained and tested on

Word2Vec features in comparison with GloVe features results. The performance of classifiers is not significant using Word2Vec features in comparison to the results of the classifiers using BoW and TF-IDF features. SVM achieved the highest accuracy of 0.88 with Word2Vec features as compared to other models because Word2Vec gives linear features set which is more suitable for SVM as compared to RF, GBC, and DT.

Table 17. Performance evaluation of classifiers using Word2Vec features.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65
RF	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80
GBC	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65	0.65
SVM	0.88	0.88	0.88	0.88	0.88	0.88	0.88	0.88	0.88	0.88

The comparison between machine learning models results on original dataset sentiment with BoW, TF-IDF, GloVe, and Word2Vec features are shown in Figure 4. SVM is significant with all features and achieved the best score with BoW, TF-IDF, and Word2Vec. This significant performance of SVM is because of its linear architecture and binary classification problem. SVM is more significant on linear data for binary classification with its linear kernel as shown in this study.

Figure 4. Performance comparison between machine learning models using original dataset and BoW, TF-IDF, GloVe, Word2Vec features.

Results on TextBlob annotated dataset

The contradictions in the users' expressed sentiments in the reviews and assigned labels can influence the sentiment classification accuracy of the models. To resolve this issue, TextBlob annotated data are used for the performance evaluation of the models. Results suggest that the performance of machine learning models is better when used with TextBlob labels than the original labels.

Results using BoW Features

The performance of models with BoW and TextBlob sentiments are shown in Table 18. Results indicate that SVM achieved its highest accuracy of the study 0.92 with TextBlob sentiments and BoW features. While the performance of other models such as RF, GBC, and DT has also been improved.

Table 18. Performance evaluation of classifiers using BoW features on TextBlob annotated dataset.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.79	0.85	0.61	0.73	0.87	0.57	0.72	0.87	0.59	0.73
RF	0.85	0.84	0.90	0.87	0.98	0.47	0.72	0.90	0.62	0.76
GBC	0.82	0.85	0.70	0.78	0.92	0.55	0.73	0.98	0.62	0.75
SVM	0.92	0.94	0.84	0.89	0.94	0.84	0.89	0.94	0.84	0.89

Results using TF-IDF Features

The performance of models with TF-IDF features and TextBlob sentiments are shown in Table 19. SVM achieves its highest accuracy score of 0.92 with TextBlob sentiment and TF-IDF features. While other models such as RF, GBC, and DT repeat their performances with TF-IDF features.

Table 19. Performance evaluation of classifiers using TF-IDF features on TextBlob annotated dataset.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.79	0.85	0.62	0.73	0.87	0.58	0.72	0.86	0.60	0.73
RF	0.84	0.85	0.88	0.87	0.98	0.51	0.74	0.91	0.65	0.78
GBC	0.83	0.86	0.73	0.79	0.92	0.57	0.75	0.89	0.64	0.77
SVM	0.92	0.92	0.88	0.90	0.96	0.78	0.87	0.94	0.82	0.88

Results using GloVe Features

Table 20 shows the performance comparison of models using GloVe features and TextBlob sentiments and it indicates that using GloVe features and TextBlob sentiments is better as compared to their performance on the original sentiments and GloVe features. Compared to the performance on the original dataset, the accuracy of the models has been improved significantly when used with TextBlob assigned sentiments. For example, the highest accuracy with GloVe features and TextBlob sentiment is 0.81 which was only 0.75 on the original sentiments. However, the performance of the machine learning models is inferior to that of BoW and TF-IDF.

Table 20. Performance evaluation of classifiers using GloVe features on TextBlob annotated dataset.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.72	0.81	0.47	0.64	0.81	0.48	0.64	0.81	0.48	0.64
RF	0.80	0.71	0.81	0.76	0.94	0.39	0.67	0.87	0.51	0.69
GBC	0.72	0.81	0.47	0.64	0.81	0.48	0.65	0.81	0.48	0.64
SVM	0.81	0.83	0.71	0.77	0.93	0.46	0.70	0.88	0.56	0.72

Results using Word2Vec Features

Table 21 shows the performance of machine learning models with Word2Vec features and TextBlob sentiments. SVM achieves significantly better accuracy with Word2Vec features as compared to GloVe features. It gives a 0.88 accuracy score which is more than GloVe features but lower than BoW and TF-IDF features. RF and GBC achieve 0.79 and 0.70 accuracy scores, respectively. The performance of DT is degraded when used with Word2Vec features.

The comparison between machine learning model results on TextBlob sentiment dataset with BoW, TF-IDF, GloVe, and Word2Vec features is given in Figure 5. SVM obtains better results with TextBlob sentiments using BoW and TF-IDF features as compared to GloVe and Word2Vec features. Similarly, the performance of other models such as RF, GBC, and DT has also been improved with the TextBlob sentiments. For the given dataset, the performance of models is good using TextBlob but these results can not be generalized for every other dataset. It is possible that a few original labels are not correct and using the TextBlob label can show better performance.

Table 21. Performance evaluation of classifiers using Word2Vec features on TextBlob annotated dataset.

Model	Accuracy	Precision			Recall			F1 Score		
		Pos.	Neg.	W avg.	Pos.	Neg.	W avg.	Pos.	Neg.	W avg.
DT	0.69	0.78	0.87	0.83	0.99	0.24	0.62	0.87	0.48	0.62
RF	0.79	0.78	0.87	0.83	0.99	0.24	0.62	0.87	0.38	0.63
GBC	0.70	0.80	0.44	0.62	0.80	0.44	0.62	0.80	0.44	0.62
SVM	0.88	0.90	0.83	0.87	0.95	0.71	0.83	0.92	0.77	0.84

Figure 5. Performance comparison between machine learning models using TextBlob dataset and BoW, TF-IDF, GloVe, Word2Vec features.

467 The performance of machine learning models is good when used with TF-IDF features extracted from
 468 the original dataset and SVM outperforms with a significant 0.89 accuracy score. TF-IDF generates a
 469 weighted feature set as compared to BoW, GloVe, and Word2Vec features which helps to improve the
 470 accuracy of learning models. On the other hand, the accuracy of DT is reduced by 1% from 72% to 71%
 471 because DT is a rule-based model that performs well on simple term frequency as compared to weighted
 472 features. Weighted features introduce complexity in the DT learning process. SVM performs well because
 473 TF-IDF provides a linear feature set with the binary class which is more suitable for SVM that performs
 474 better being the linear model. The performance of machine learning models is improved with TextBlob
 475 data annotation. Machine learning models perform well with TF-IDF and BoW features and SVM obtains
 476 the highest accuracy of 0.92 accuracy score using TextBlob labels.

477 Performance of Deep Learning Models

478 To compare the performance of the proposed approach with the latest deep learning approach, experiments
 479 have been performed using several deep learning models. For this purpose, state-of-the-art deep learning
 480 models are used such as LSTM, CNN-LSTM, and Gated Recurrent Unit (GRU). The architecture of used
 481 deep learning models is provided in Figure 6. These models are used with the TextBlob annotated dataset
 482 owing to the superior results on the dataset from machine learning models.

483 The performance of deep learning models is also good similar to machine learning models, as shown
 484 in Table 22. CNN-LSTM achieves a 0.90 accuracy score while GRU has a 0.86 accuracy. The results of
 485 deep learning models are shown in Table 6. Overall, the performance of deep learning models is slightly
 486 lower than the machine learning models. Regarding the machine learning model, SVM gives the highest
 487 accuracy of 0.92 while the deep learning model CNN-LSTM achieves a 0.90 accuracy. The significant
 488 performance of machine learning models is because of handcrafted TF-IDF weighted features.

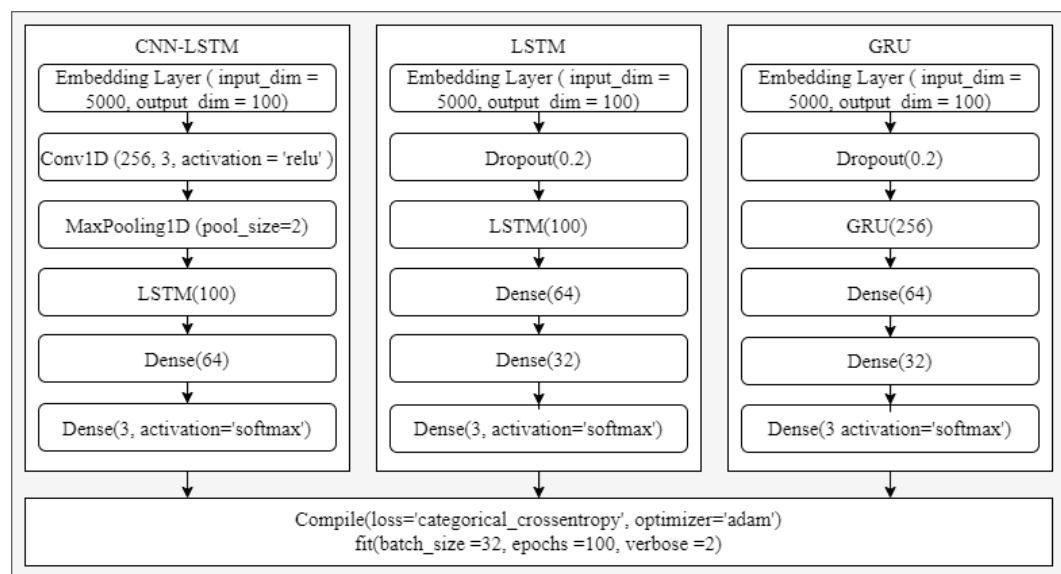

Figure 6. LSTM, CNN-LSTM, and GRU architectures .

Table 22. Performance analysis of deep learning models

Model	Accuracy	Class	Precision	Recall	F1 Score
LSTM	0.80	Neg.	0.83	0.79	0.81
		Pos.	0.93	0.93	0.94
		Avg.	0.88	0.87	0.87
CNN-LSTM	0.90	Neg.	0.78	0.88	0.83
		Pos.	0.96	0.91	0.93
		Avg.	0.87	0.90	0.88
GRU	0.86	Neg.	0.84	0.88	0.86
		Pos.	0.88	0.83	0.85
		Avg.	0.86	0.86	0.86

Performance Analysis with State-of-The-Art Approaches

Performance analysis has been carried out to analyze the performance of the proposed approach with other state-of-the-art approaches that utilize the IMDB movie reviews analysis. Comparison results are provided in Table 23. Results indicate that the proposed methodology can achieve competitive results to that of state-of-the-art approaches. The use of SVM with TF-IDF and BoW using the TextBlob technique provides an accuracy of 92% which is better than the state-of-the-art approaches.

Statistical T-test

The T-test is performed in this study to show the statistical significance of the proposed approach (Omar et al., 2021). The T-test is applied to SVM results with the proposed approach and original dataset. The output from the T-test favors either null hypothesis or alternative hypothesis.

- Accept Null Hypothesis: This means that the compared results are statistically equal.
- Reject Null Hypothesis: This means that the compared results are not statistically equal.

The output values of T-test in terms of T-statistic and critical Value are shown in Table 24. T-test infers that the null hypothesis can be rejected in favor of the alternative hypothesis because the T-statistic value is less than the critical value indicating that the compared values are statistically different from each other.

CONCLUSION

With an ever-growing production of cinema movies, web series, and television dramas, a large number of reviews can be found on social platforms and movies websites like IMDB. Sentiment analysis of such

Table 23. Performance analysis of the proposed methodology.

Year	Reference	Model	Accuracy
2016	(Sahu and Ahuja, 2016)	RF	0.90
2017	(Yenter and Verma, 2017)	CNN+LSTM	0.895
2017	(Giatsoglou et al., 2017)	BoW-DOUBLE and Average emotion-DOUBLE	0.83
2018	(Mathapati et al., 2018)	CNN	0.89
2019	(Ali et al., 2019)	CNN+LSTM	0.89
2019	(Bodapati et al., 2019)	LSTM + DNN	0.885
2020	(Tripathi et al., 2020)	TF-IDF +LR	0.891
2020	(Qaisar, 2020)	LSTM	0.899
2020	(Shaukat et al., 2020)	NN	0.91
2021	(Jain and Jain, 2021a)	CNN	0.883
2021	(Nafis and Awang, 2021)	SVM + (SVM-RFE)	0.895
2021	(Jain and Jain, 2021b)	NB+ ARM	0.784
2021	Proposed	SVM + TextBlob +BoW & TF-IDF	0.92

Table 24. Statistical T-test output values

Student T-test output parameters	Output value
T-statistic	-0.182
Critical Value	0.000

507 reviews can provide insights about the movies, their team, and cast to millions of viewers. This study
508 proposes a methodology to perform sentiment analysis on the movie reviews using supervised machine
509 learning classifiers to assist the people in selecting the movies based on the popularity and interest of the
510 reviews. Four machine learning algorithms including DT, RF, GBC, and SVM are utilized for sentiment
511 analysis that is trained on the dataset preprocessed through a series of steps. Moreover, four feature
512 extraction approaches including BoW, TF-IDF, GloVe, and Word2Vec are investigated for their efficacy in
513 extracting the meaningful and effective features from the reviews. Results indicate that SVM achieves
514 the highest accuracy among all the classifiers with an accuracy of 89.55% when trained and tested using
515 TF-IDF features. The performance using BoW features is also good with an accuracy of 87.25%. Contrary
516 to BoW which counts the occurrence of unique tokens, TF-IDF also records the importance of rare terms
517 by assigning a higher weight to rare terms and perform better than BoW. However, the performance of the
518 classifiers is greatly affected by GloVe and Word2Vec features which suggest that word embedding does
519 not work well with the movie review dataset. For improving the performance of models and reducing
520 the influence of contradictions found in the expressed sentiments and assigned labels, TextBlob is used
521 for data annotation. Experimental results on TextBlob annotated dataset indicates that SVM achieves the
522 highest accuracy of 92% with TF-IDF features. Compared to the standard dataset, the TextBlob assigned
523 labels result in better performance from the models. The performance of deep learning models is slightly
524 lower than machine learning models with the highest accuracy of 0.90 by the CNN-LSTM. Despite the
525 equal number of positive and negative reviews used for training, the prediction accuracy for the positive
526 and negative classes is different. Precision, recall, and F1 score indicate the models have a good fit, and
527 performance evaluation metrics are in agreement. The current study excludes the neutral class due to a
528 low number of samples and experiments are performed using positive and negative classes. Consequently,
529 the accuracy may have been higher as compared to that with three classes. Similarly, probable class
530 imbalance by adding neutral class samples is not investigated and is left for the future. We intend to
531 perform further experiments using movie reviews datasets from other sources in the future. Furthermore,
532 the study on finding the contradictions in the sentiments expressed in the reviews and the assigned labels
533 is also under consideration.
