Research proposed in this article presents a novel improved version of widely adopted firefly algorithm and its application for tuning and optimising XGBoost classifier hyper-parameters for network intrusion detection. One of the greatest issues from the domain of network intrusion detection systems are relatively high false positives and false negatives rates. In the proposed study, by using XGBoost classifier optimised with improved firefly algorithm, this challenge is addressed. Based on the established practice from the modern literature, proposed improved firefly algorithm was first validated on 28 well-known CEC2013 benchmark instances and comparative analysis with original firefly algorithm and other state-of-the-art metaheuristics was conducted. Afterwards, devised method was adopted and tested for XGBoost hyper-parameters optimisation and the tuned classifier was tested on the widely used benchmarking NSL-KDD dataset and more recent USNW-NB15 dataset for network intrusion detection. Obtained experimental results prove that the proposed metaheuristics has significant potential in tackling machine learning hyper-parameters optimisation challenge and that it can be used for improving classification accuracy and average precision of network intrusion detection systems.

12 **ABSTRACT**

13 Research proposed in this article presents a novel improved version of widely adopted firefly algorithm
14 and its application for tuning and optimising XGBoost classifier hyper-parameters for network intrusion
15 detection. One of the greatest issues from the domain of network intrusion detection systems are
16 relatively high false positives and false negatives rates. In the proposed study, by using XGBoost classifier
17 optimised with improved firefly algorithm, this challenge is addressed. Based on the established practice
18 from the modern literature, proposed improved firefly algorithm was first validated on 28 well-known
19 CEC2013 benchmark instances and comparative analysis with original firefly algorithm and other state-of-
20 the-art metaheuristics was conducted. Afterwards, devised method was adopted and tested for XGBoost
21 hyper-parameters optimisation and the tuned classifier was tested on the widely used benchmarking
22 NSL-KDD dataset and more recent USNW-NB15 dataset for network intrusion detection. Obtained
23 experimental results prove that the proposed metaheuristics has significant potential in tackling machine
24 learning hyper-parameters optimisation challenge and that it can be used for improving classification
25 accuracy and average precision of network intrusion detection systems.

28 **INTRODUCTION**

29 The firefly algorithm (FA), proposed by Yang (2009), is a swarm intelligence algorithm designed for
30 exploration, exploitation, and local search of solutions, inspired by social behaviour and flashing activities
31 exhibited by the fireflies. The original FA algorithm is tested against the updated CEC2013 benchmark
32 function set in this article. Also, this article presents the performance of a well-known XGBoost classifier,
33 whose parameters have been optimised using the FA algorithm for the problem of Network Intrusion
34 Detection (NIDS) optimisation. Different NIDS have a simple purpose: to monitor network traffic and
35 detect malicious user activities. They are usually implemented as nodes on strategic points in the network.

36 According to Hodo et al. (2016), NIDS are reliable when dealing with outside threats but are inefficient
37 for determining the extent of damage from an attack. Core issues with these systems are rates of false
38 positives (FP) and false negatives (FN). FPs occur when the system wrongly classifies regular activities as
39 malicious, and FNs occur when the system fails to properly classify malicious activities as such. Different
40 approaches are used to attempt to solve these issues. Machine learning (ML) algorithms present one
41 possible type of solution. ML solutions attempt to find optimal hyper-parameters to optimise classifiers
42 for different network activity datasets to increase detection efficiency.

43 Among ML algorithms, there are different approaches for optimising the ML model (Ikram et al.,
44 2021; Thaseen and Kumar, 2017). Swarm intelligence (SI) algorithms usually have good performance

(Bergstra et al., 2011; Jiang et al., 2020; Bacanin et al., 2020). This study tests the performance of a well-known XGBoost classifier for classifying NIDS events from the NSL-KDD (Network Security Laboratory - Knowledge Discovery and Data Mining) dataset (Dhanabal and Shantharajah, 2015), which are, according to Protić (2018), effective in evaluating intrusion detection systems. The second experiment test the performance of the XGBoost classifier on a more recent NIDS UNSW-NB15 dataset (Moustafa and Slay, 2015). The hyper-parameters of the classifier are optimised using a proposed improved FA algorithm.

The motivation behind the approach suggested in this research was to enhance the basic implementation of FA further and improve the classification capabilities of XGBoost classifier. According to the no free lunch theorem, an universal optimisation algorithm that can solve all optimisation problems does not exist. Additionally, it is always possible to improve the existing optimisation algorithms. In this context, the research proposed in this paper is focused on improving the solving of the very important challenge in intrusion detection systems by using the XGBoost classifier, and in order to do so, a new, improved FA algorithm has been developed. The most important contributions of this paper are three-fold:

- A novel enhanced FA metaheuristics has been developed by specifically targeting the well-known deficiencies of the original FA implementation;
- The developed method was later used to help establish the proper hyper-parameters values and improve the XGBoost classifier accuracy for the intrusion detection classification problem;
- The proposed method results were compared with other notable swarm intelligence algorithms, which were further investigated for the XGBoost optimisation problem.

The rest of the paper is structured as follows. The following section introduces the problem of optimisation and various types of optimisation algorithms, focusing on related work in machine learning algorithms. The paper presents the proposed model, describes the set of CEC2013 functions, the firefly algorithm's performance assessed by this benchmark, gives an overview of the experimental setup for the second part of the paper. Results, comparative analysis and result discussion section, follow the materials and methods section. Finally, the conclusion of this paper is given with suggested future work propositions.

BACKGROUND

This section introduces NIDS, the problem of optimisation, in general, and concerning NIDS, and different algorithmic approaches to optimising NIDS network event classification methods. Different machine learning approaches are presented towards the end of the section, leading up to the overview of works related to this problem.

The Problem of Network Intrusion Detection

In the last two decades, the web has become the centre stage for many businesses, social, political and other activities and transactions that all happen on the global network. Endpoints of those network transactions are users, usually located within smaller computer networks, such as companies, small Internet provider sub-networks etc. Therefore, security has become an important issue for the contemporary Internet user, even though different intrusion detection solutions have been around for almost forty years (Neupane et al., 2018). There are many solutions created to protect users from malicious activities and attacks (Patel et al., 2010; Mugunthan, 2019).

According to Neupane et al. (2018), traditional NIDS come in the forms of firewalls, and statistical detection approaches usually applied either on the transport or the application layers, which require extensive setup, policy configurations etc. More modern systems use sophisticated approaches. According to Sathesh (2019), ML is used to solve the problem of intrusion detection, even though these approaches have different challenges, as reported by Jordan and Mitchell (2015). Regardless, ML approaches are efficient in finding optimal solutions for time-consuming problems, such as training efficient NIDS network event classifiers. Different solutions are based on various types of ML methods, such as artificial neural networks (ANN), evolutionary algorithms (EA), and other supervised and unsupervised learning methods, according to Verwoerd and Hunt (2002).

94 When creating and evaluating a NIDS, it is important to measure its performance accurately. For this
95 reason, previously mentioned false positives (FP) and false negative (FN) measurements are used together
96 with true positive (TP) and true negative (TN) measurements to correctly evaluate the classification
97 accuracy of a NIDS, according to the general formula shown in Equation 1.

$$ACC = (TP + TN) / (TP + FP + TN + FN) \quad (1)$$

98 From values TP, TN, FP and FN, it is possible to also determine the system's sensitivity, specificity,
99 fallout, miss rate, and prevision through methods presented in Equations 2-6:

$$Sensitivity = TP / (TP + FN) \quad (2)$$

$$Specificity = TN / (TN + FP) \quad (3)$$

$$Fallout = FP / (TN + FP) \quad (4)$$

$$Missrate = FN / (TP + FN) \quad (5)$$

$$Precision = TP / (TP + FP) \quad (6)$$

100 Optimisation and Optimisation Algorithms

101 Optimisation aims to find an optimal or near-optimal solution for a certain problem within the given set of
102 constraints. Many population-based stochastic meta-heuristics were developed for solving the problem of
103 optimisation, according to Beheshti and Shamsuddin (2013).

104 Non-deterministic polynomial-time-hard problems are hard to solve with traditional deterministic
105 algorithms. They can take a long time to complete on commonly available hardware. Therefore, these
106 solutions are usually impractical.

107 On the other hand, optimal solutions to these types of problems can be found using stochastic meta-
108 heuristics, which do not guarantee an optimal solution, but acceptable sub-optimal ones in reasonable
109 time-frames, according to Spall (2011). Commonly, these algorithms are labelled as Machine Learning
110 Algorithms (MLA).

111 Swarm Intelligence Algorithms

112 A special type of nature-inspired stochastic meta-heuristic MLA are population-based algorithms, among
113 which are swarm intelligence algorithms (SIA). These algorithms inspire different naturally occurring
114 systems, where individual self-organising agents interact with each other and their environment without a
115 centralised governing component. These systems give an impression of globally coordinated behaviour
116 and have inexpensive abilities in solving very demanding optimisation problems (Mavrovouniotis et al.,
117 2017).

118 The most notable and popular methods that have proven themselves as powerful optimiser with
119 respectable performances include the ant colony optimisation (ACO) introduced by Dorigo et al. (2006),
120 artificial bee colony (ABC) proposed by Karaboga and Basturk (2007), particle swarm optimisation (PSO)
121 developed by Kennedy and Eberhart (1995), as well as the FA, introduced by Yang (2009) and used as a
122 foundation for the algorithm proposed in this paper. More recent algorithms that have shown good results
123 include the grey wolf optimiser (GWO) (Mirjalili et al., 2014), moth search (MS) (Wang, 2018), monarch
124 butterfly algorithm (MBA) (Wang et al., 2019), whale optimisation algorithm (WOA) (Mirjalili and Lewis,
125 2016), and the Harris hawk's optimisation (HHO) (Heidari et al., 2019). Additionally, the differential
126 evolution algorithm (Karaboğa and Okdem, 2004) and the co-variance matrix adaptation (Igel et al., 2007)
127 approaches have also recently exhibited outstanding performances. Recently, algorithms inspired by the
128 properties of the mathematical functions gained popularity among scientific circles, and the most notable
129 algorithm is the sine-cosine algorithm (SCA), which was proposed by Mirjalili (2016). SCA was also
130 utilised in this research to hybridise the basic FA search.

131 The application of the metaheuristics discussed take on a wide spectrum of different problems with
132 NP-hardness in the information technologies field. Some of the such applications are with the problem of
133 global numerical optimisation (Bezdan et al., 2021b), scheduling of tasks in the cloud reliant systems
134 (Bezdan et al., 2020b; Bacanin et al., 2019a; Zivkovic et al., 2021b), the problems of wireless sensors
135 networks such as localisation of nodes and the network lifetime prolonging (Zivkovic et al., 2020a;

Bacanin et al., 2019b; Zivkovic et al., 2020b; Bacanin et al., 2022b; Zivkovic et al., 2021d), artificial neural networks optimisation (Strumberger et al., 2019; Milosevic et al., 2021; Bezdan et al., 2021c; Cuk et al., 2021; Stoean, 2018; Bacanin et al., 2022c; Gajic et al., 2021; Bacanin et al., 2022a; Jnr et al., 2021; Bacanin et al., 2021a, 2022d, 2021b,c), histological slides or MRI classifier optimisation (Bezdan et al., 2020a, 2021a; Lichtblau and Stoean, 2019; Postavaru et al., 2017; Basha et al., 2021), and last but not least the COVID-19 case prediction (Zivkovic et al., 2021a,c).

These algorithms, on their own, have strengths and weaknesses when applied to different problems, and often, they are used to optimise different higher-level models and their hyper-parameters instead of being used to perform classification on their own. This article presents this synthesis of an optimisation algorithm used for hyper-parameter tuning and optimising a higher-order classification system.

Related Work

Applications of ML algorithms have been reported in many scientific and practical fields in the industry, as well as for NIDS, as reported by Tama and Lim (2021) and Ahmed and Hamad (2021). Specifically for the problem of NIDS optimisation, solutions exist that are based on particle swarm optimisation (PSO) (Jiang et al., 2020), artificial neural networks (ANN) and support vector machines (SVM) (Mukkamala et al., 2002), naive Bayesian (NB) (Mukherjee and Sharma, 2012), K-nearest neighbour (KNN) (Govindarajan and Chandrasekaran, 2009), and in combination with other classifiers, as presented by Dhaliwal et al. (2018), Ajdani and Ghaffary (2021) and Bhati et al. (2021).

METHODS

The original implementation of the FA is shown in this section, followed by the descriptions of known and observed flaws of the original FA. The section suggests improvements to the original algorithm to address the described flaws.

The original version of the Firefly Algorithm

Yang (2009) has suggested a swarm intelligence system that was inspired by the fireflies' lighting phenomenon and social behaviour. Because the behaviour of actual fireflies is complicated, the FA metaheuristics model, with certain approximations, was proposed.

The fitness functions are modelled using the firefly's brightness and attraction. In most FA implementations, attractiveness depends on the brightness, determined by the objective function's value. In the case of minimisation problems, it is written as Yang (2009):

$$I(x) = \begin{cases} 1 / f(x) & , \text{ if } f(x) > 0 \\ 1 + |f(x)| & , \text{ if } f(x) \leq 0 \end{cases} \quad (7)$$

where $I(x)$ is the attractiveness and $f(x)$ represents the objective function's value at x , which is the location.

Therefore, the attractiveness of a firefly is indirectly proportional to the distance from the source of light (Yang, 2009):

$$I(r) = \frac{I_0}{1 + \gamma \times r^2} \quad (8)$$

When modelling systems where the environment absorbs the light, the FA uses the light absorption coefficient parameter γ . $I(r)$ and I_0 are the intensities of the light at the distance of r and the source. Most FA implementations combine effects of the inverse square law for distance and γ to approximate the following Gaussian form (Yang, 2009):

$$I(r) = I_0 \cdot e^{-\gamma \times r^2} \quad (9)$$

As indicated in Equation (10), each firefly employs β (representing attractiveness), which is proportionate to the intensity of the firefly's light, which is reliant on distance.

$$\beta(r) = \beta_0 \cdot e^{-\gamma \times r^2} \quad (10)$$

where β_0 represents the attractiveness at $r = 0$. However, Equation (10) is commonly swapped for Equation (11) (Yang, 2009):

$$\beta(r) = \beta_0 / (1 + \gamma \times r^2) \quad (11)$$

Based on Equation 11, the equation for a random firefly i , moving in iteration $t + 1$ to a new location x_i in the direction of another firefly j , which has a greater fitness value, according to the original FA, is (Yang, 2009):

$$x_i^{t+1} = x_i^t + \beta_0 \cdot e^{-\gamma \times r_{i,j}^2} (x_j^t - x_i^t) + \alpha^t (\kappa - 0.5) \quad (12)$$

where α is the randomisation parameter, κ is the random uniformly distributed number, and $r_{i,j}$ is the distance between fireflies i and j . Values that often give good results for most problems for β_0 and α are 1 and $[0, 1]$. The $r_{i,j}$ is calculated as follows, and represents the Cartesian distance:

$$r_{i,j} = \|x_i - x_j\| = \sqrt{\sum_{k=1}^D (x_{i,k} - x_{j,k})^2} \quad (13)$$

where D is the number of parameters of a specific problem.

Reasons for Improvements

The original FA has performed exceptionally for many benchmarks (Yang and He, 2013) and practical problems (Strumberger et al., 2019). Past research suggests that the original FA has several flaws regarding exploration and an inappropriate intensification-diversification balance (Strumberger et al., 2017; Xu et al., 2021; Bacanin and Tuba, 2014). The lack of diversity is noticeable in early iterations, when the algorithm cannot converge to optimum search space areas in certain runs, resulting in low mean values. In such cases, the original FA search technique (Equation 12), which mostly performs exploitation, is incapable of directing the search to optimal domains. In contrast, the FA achieves satisfactory results when random solutions are created randomly in optimal or near-optimal areas during the initialisation phase.

An examination of the original FA search equation (Equation 12) reveals that it lacks an explicit exploration technique. Some FA implementations employ the dynamic randomisation parameter α , which is continuously reduced from its starting value α to the specified threshold α_{min} , as shown in Equation (14). As a result, at the start of a run, exploration is prioritised, whereas subsequent iterations shift the balance between intensity and diversification toward exploitation (Wang et al., 2017). However, based on simulations, it is concluded that the use of dynamic α is insufficient to improve FA exploration skills, and the suggested technique only somewhat alleviates this problem.

$$\alpha^{t+1} = \alpha^t \cdot (1 - t/T), \quad (14)$$

where t and $t + 1$ are current and next iterations, and T is the maximum iteration count in a single run.

Past research has shown that FA exploitation abilities are effective in addressing a variety of tasks, and FA is characterised as a metaheuristic with substantial exploitation capabilities (Strumberger et al., 2017; Xu et al., 2021; Bacanin and Tuba, 2014).

Novel FA Metaheuristics

This work proposes an improved FA that tackles the original FA's flaws by using the following procedures:

- A technique for explicit exploration based on the exhaustiveness of the answer;
- gBest chaotic local search (CLS) approach.
- Hybridisation with SCA search by doing either FA or SCA search at random in each cycle based on a produced pseudo-random value.

The FA's intensification may be improved further by applying the CLS mechanism, as demonstrated in the empirical portion of this work. A novel FA is dubbed chaotic FA with improved exploration due to proposed modifications (CFAEE-SCA).

189 **Explicit Exploration Mechanism**

The purpose of this mechanism is to ensure the convergence to the best section of the search space early on, while facilitating exploration around the parameter bounds of the current best individual x^* later on. Each solution is represented using an additional attribute *trial*. It increases this attribute when it cannot further improve the solution with the original FA search (Equation 12). When the *trial* parameter reaches a set *limit*, the individual is swapped for a random one picked from the search space in the same way as in the setup phase:

$$x_{i,j} = l_j + (u_j - l_j) \cdot rand, \quad (15)$$

190 where $x_{i,j}$ is the j -th component of i -th individual, u_j and l_j are the upper and lower search boundaries of
191 the j -th parameter, and *rand* is a random number in range $[0, 1]$, from a uniform distribution.

192 A complete solution is one for which *trial* exceeds the *limit*. This term was adapted from the well-
193 known ABC metaheuristics (Karaboga and Basturk, 2008), which have efficient exploration mechanisms
194 (Moradi et al., 2018).

When the algorithm fails to find appropriate areas of the search space, replacing the exhausted solution with a pseudo-random person improves search performance early on. Later on, this type of substitution wastes functions evaluations. As a result, in subsequent iterations, the random replacement technique is replaced by the directed replacement mechanism around the bottom and higher parameter values of the population's solutions:

$$x_{i,j} = Pl_j + (Pu_j - Pl_j) \cdot rand, \quad (16)$$

195 where Pl_j and Pu_j are the lowest and highest values of the j -th component from the whole population P .

196 **The gBest CLS Strategy**

197 Chaos is responsive to the initial conditions of non-linear and deterministic systems (Alatas, 2010).
198 Chaotic search is more efficient than the ergodic (dos Santos Coelho and Mariani, 2008) because many
199 sequences can be created by modifying the initial values.

Literature reports many chaotic maps. After testing, it was determined that the logistic map yields the most favourable results in the case of the suggested innovative FA. The logistic map has been used in a variety of swarm intelligence methodologies so far (Li et al., 2012; Chen et al., 2019; Liang et al., 2020). The logistic map used by the proposed method is defined in K steps as:

$$\sigma_{i,j}^{k+1} = \mu \sigma_{i,j}^k (1 - \sigma_{i,j}^k), \quad k = 1, 2, \dots, K, \quad (17)$$

200 where $\sigma_{i,j}^k$ and $\sigma_{i,j}^{k+1}$ are chaotic variable for the i -th solution's j -th component in steps k and $k + 1$, and μ
201 is a control variable. $\sigma_{i,j} \neq 0.25, 0.5$ and 0.75 , $\sigma_{i,j} \in (0, 1)$ and μ is set to 4. This value was determined
202 empirically by Liang et al. (2020).

The proposed method integrates the global best (gBest) CLS strategy. The chaotic search is performed around the x^* solution. Equations (18) and (19) show how a new x^* (x'^*) is created in each step k , for component j of x^* :

$$x'_j = (1 - \lambda)x_j^* + \lambda S_j \quad (18)$$

$$S_j = l_j + \sigma_j^k (u_j - l_j) \quad (19)$$

where Equation (17) determines σ_j^k , and λ is the dynamic shrinkage parameter dependant on FFE (current fitness function evaluation) and $maxFFE$ (maximum number of fitness function evaluations):

$$\lambda = (maxFFE - FFE + 1) / maxFFE \quad (20)$$

203 Better exploitation-to-exploration equilibrium is formed around the x^* by employing dynamic *lambda*.
204 Earlier in the execution, a larger search radius around the x^* was performed, whereas later, a fine-tuned
205 exploitation commenced. When the maximum number of iterations is used as the termination condition,
206 the FFE and $maxFFE$ can be substituted with t and T .

207 The CLS strategy is used to enhance x^* in K steps. If the x'^* achieves greater fitness than the x^* , the
208 CLS method is ended, and the x^* is replaced with x'^* . However, if the x^* could not be improved in K
209 stages, it is maintained in the population.

210 **SCA search**

SCA proposes the use of the following updating Equation (21) in both phases:

$$\begin{aligned} X_i^{t+1} &= X_i^t + r_1 \times \sin(r_2) \times |r_3 P_i^t - X_i^t| \\ X_i^{t+1} &= X_i^t + r_1 \times \cos(r_2) \times |r_3 P_i^t - X_i^t| \end{aligned} \quad (21)$$

211 where X is the position of the current solution in the i -th dimension after the t -th iteration, P_i is the
212 destination at the i -th dimension, and r_1 , r_2 and r_3 are random numbers.

213 A combination of Equations (21) is show in Equation (22):

$$X_i^{t+1} = \begin{cases} X_i^{t+1} = X_i^t + r_1 \times \sin(r_2) \times |r_3 P_i^t - X_i^t|, & r_4 < 0.5 \\ X_i^{t+1} = X_i^t + r_1 \times \cos(r_2) \times |r_3 P_i^t - X_i^t|, & r_4 \geq 0.5 \end{cases} \quad (22)$$

214 where r_4 is a random value in range $[0, 1]$.

215 The preceding equation demonstrates that the algorithm's four main parameters are r_1 , r_2 , r_3 , and
216 r_4 . The r_1 parameter determines the region (movement direction) of the next location; it might be inside
217 or outside the area between the destination and solution. The r_2 parameter specifies the amplitude and
218 direction of the movement (towards the destination or outwards). The r_3 parameter assigns a random
219 weight to the destination in order to reduce ($r_3 < 1$) or accentuate ($r_3 > 1$) the impacts of the destination in
220 the distance definition. The r_4 parameter is used to alternate between sine and cosine components.

221 The SCA search algorithm is included in the proposed method in the following fashion. Each cycle
222 generates a pseudo-random number. If the resulting value is more than 0.5, the FA search algorithm does.
223 Otherwise, it executes the SCA search described in Equation (22).

224 **Chaotic FA with Enhanced Exploration and SCA search Pseudo-Code**

225 A few factors should be examined to efficiently include the exploration mechanism and gBest CLS
226 approach into the original FA. First, as previously indicated, the random replacement method should be
227 used in the early stages of execution, while the guided one would produce superior outcomes later on.
228 Second, the gBest CLS technique would not produce substantial gains in early iterations since the x^*
229 would still not converge to the optimal area, wasting *FFE*s.

230 The extra control parameter ψ is introduced to govern the behaviour as mentioned earlier. If $t < \psi$,
231 the exhausted population solutions are replaced randomly (Equation (15) without activating the gBest
232 CLS. Otherwise, it executes the guided replacement mechanism (Equation (16) and activates the gBest
233 CLS.

234 The original FA search suggested approach uses dynamic *alpha* to fine-tune, according to Equation
235 (14). Based on the pseudo-random value, the method alternates between FA and SCA in each round.

236 Taking everything above into account, Algorithm 1 summarises the pseudo-code of the proposed
237 CFAEE-SCA.

238 The flowchart of the proposed CFAEE-SCA algorithm is given in the Figure 1.

239 **The CFAEE-SCA Complexity and Drawbacks**

240 Because the most computationally costly portion of the swarm intelligence algorithm is the objective
241 evaluation (Yang and He, 2013), the number of FFEs may be used to assess the complexity of the method.

242 The basic FA evaluates objective functions during the startup and solution update stages. When
243 updating solutions, the FA utilises one main loop for T iterations and two inner loops that go through N
244 solutions, according to the Equation (12) (Yang and He, 2013).

245 Basic FA metaheuristics have a worst-case complexity of $O(N) + O(N^2 \cdot T)$, including the initialisation
246 phase. However, if N is large enough, one inner loop may be used to rate the beauty or brightness of all
247 fireflies using sorting algorithms. Complexity in this situation is $O(N) + O(N \cdot T \cdot \log(N))$ (Yang and He,
248 2013).

249 Because of the explicit exploration mechanism and the gBest CLS method, the suggested CFAEE-
250 SCA has a higher complexity than the original FA. In the worst-case situation, if $limit = 0$, all solutions
251 will be replaced in every iteration, and if $\phi = 0$, the gBest CLS approach will be activated during
252 the whole run. Assuming that K is set to 4, the worst-case CFAEE-SCA complexity is stated as:
253 $O(N) + O(T \cdot N^2) + O(T \cdot N) + O(4 \cdot T)$. In practice, however, the complexity is substantially lower due
254 to *limit* and ψ control parameter modifications.

Algorithm 1 The CFAEE-SCA pseudo-code

```

Initialise control parameters  $N$  and  $T$ 
Initialise search space parameters  $D$ ,  $u_j$  and  $l_j$ 
Initialise CFAEE-SCA parameters  $\gamma$ ,  $\beta_0$ ,  $\alpha_0$ ,  $\alpha_{min}$ ,  $K$  and  $\phi$ 
Initialise random population  $P_{init} = \{x_{i,j}\}, i = 1, 2, 3 \dots, N; j = 1, 2, \dots, D$  using Equation (15) in the search space
while  $t < T$  do
    for  $i = 1$  to  $N$  do
        for  $z = 1$  to  $i$  do
            if  $I_z < I_i$  then
                Generate pseudo-random value  $rnd$ 
                if  $rnd > 0.5$  then
                    Perform FA search
                    Move solution  $z$  in the direction of individual  $i$  in  $D$  dimensions (Equation (12))
                    Attractiveness changes with distance  $r$  as  $\exp[-\gamma r]$  (Equation (10))
                    Evaluate new solution, swap the worse individual for a better one and update light intensity
                else
                    Perform SCA search
                    Move solution  $z$  in  $D$  dimensions (Equation (22))
                end if
            end if

        Swap solutions where  $trial = limit$  for others, using Equation (16)
        for  $k = 1$  to  $K$  do
            Perform gBest CLS around the  $x^*$  using Equations (17–19) and generate  $x'^*$ 
            Retain better solution between  $x^*$  and  $x'^*$ 
        end for
    end if
    Update parameters  $\alpha$  and  $\lambda$  using Equations (14) and (20)
end while
Return the best individual  $x_*$  from the population
Post-process results and perform visualisation

```

255 The CFAEE-SCA has certain drawbacks over the original design, including the use of new control
256 parameters $limit$ and ψ . However, the values of these parameters may be easily determined by performing
257 empirical simulations. Furthermore, as proven in the next sections, the CFAEE-SCA outperforms the
258 original FA for benchmark tasks and the XGBoost optimisation challenge from the machine learning
259 domain.

260 RESULTS OF PROPOSED ALGORITHM AGAINST STANDARD CEC2013 261 BENCHMARK FUNCTION SET

262 The CEC2013 benchmark functions suite consists of 28 challenging benchmark function instances
263 belonging to the different classes. Functions 1-5 belong to the group of uni-modal instances, functions
264 6-20 are multi-modal instances, while functions 21-28 belong to the composite functions family. The
265 CEC2013 functions list is presented in Table 1. The challenge is to minimise the functions. Each class of
266 functions has its purpose - uni-modal benchmarks test the exploitation, multi-modal benchmarks target
267 exploration. In contrast, the composite benchmarks are utilised to assess the algorithm's performances
268 due to their complex nature.

269 The basic implementation of FA and the proposed CFAEE-SCA algorithms have been validated
270 against five recent cutting-edge metaheuristics tested on the same benchmark function set. The competitor
271 metaheuristics included practical genetic algorithm (RGA) (Haupt and Haupt, 2004), gravitational search
272 algorithm (GSA) (Rashedi and Nezamabadi-pour, 2012), disruption gravitational search algorithm (D-
273 GSA) (Sarafrazi et al., 2011), clustered gravitational search algorithm (BH-GSA) (Shams et al., 2015), and

attractive repulsive gravitational search algorithm (AR-GSA) (Zandevakili et al., 2019). The introduced CFAEE-SCA method has been tested in the same way as proposed in Zandevakili et al. (2019). That publication was utilised to reference the results of other methods included in the comparative analysis. Authors Zandevakili et al. (2019) proposed a novel version of the GSA by adding the attracting and repulsing parameters to enhance both diversification and intensification phases. It is worth noting that the authors have implemented all algorithms used by Zandevakili et al. (2019) on their own and tested them independently by using the same experimental setup proposed by Zandevakili et al. (2019). The novel CFAEE-SCA has been implemented and verified on all 28 benchmark functions with thirty dimensions ($D = 30$), together with the basic FA implementation.

Table 1. CEC2013 functions used in the benchmark experiments

No	Functions	Initial range
Uni-modal Functions		
1	Sphere function	$[-100, 100]^D$
2	Rotated High Conditioned Elliptic Function	$[-100, 100]^D$
3	Rotated Bent Cigar Function	$[-100, 100]^D$
4	Rotated Discus Function	$[-100, 100]^D$
5	Different Powers Function	$[-100, 100]^D$
Basic multi-modal Functions		
6	Rotated Rosenbrock's Function	$[-100, 100]^D$
7	Rotated Schaffer's F7 Function	$[-100, 100]^D$
8	Rotated Ackley's Function	$[-100, 100]^D$
9	Rotated Weierstrass Function	$[-100, 100]^D$
10	Rotated Griewank's Function	$[-100, 100]^D$
11	Rastrigin's Function	$[-100, 100]^D$
12	Rotated Rastrigin's Function	$[-100, 100]^D$
13	Non-Continuous Rotated Rastrigin's Function	$[-100, 100]^D$
14	Schwefel's Function	$[-100, 100]^D$
15	Rotated Schwefel's Function	$[-100, 100]^D$
16	Rotated Katsuura Function	$[-100, 100]^D$
17	Lunacek Bi_Rastrigin Function	$[-100, 100]^D$
18	Rotated Lunacek Bi_Rastrigin Function	$[-100, 100]^D$
19	Expanded Griewank's plus Rosenbrock's Function	$[-100, 100]^D$
20	Expanded Schaffer's F6 Function	$[-100, 100]^D$
Composite Functions		
21	Composite Function 1 (n = 5, Rotated)	$[-100, 100]^D$
22	Composite Function 2 (n = 3, Unrotated)	$[-100, 100]^D$
23	Composite Function 3 (n = 3, Rotated)	$[-100, 100]^D$
24	Composite Function 4 (n = 3, Rotated)	$[-100, 100]^D$
25	Composite Function 5 (n = 3, Rotated)	$[-100, 100]^D$
26	Composite Function 6 (n = 5, Rotated)	$[-100, 100]^D$
27	Composite Function 7 (n = 5, Rotated)	$[-100, 100]^D$
28	Composite Function 8 (n = 5, Rotated)	$[-100, 100]^D$

In tables 2, 3 and 4, the results of the CFAEE-SCA on CEC2013 instances with 30 dimensions and 51 independent runs for uni-modal, multi-modal and composite functions, respectively, have been evaluated against six other swarm intelligence metaheuristics. As mentioned before, the same simulation conditions were utilised as in (Zandevakili et al., 2019), with the same stop criteria for the function of the number of evaluation fitness functions with the maximum number being $1.00e + 05$. Furthermore, the experiments have been conducted with 50 solutions in the population ($N = 50$).

Convergence graphs of the proposed CFAEE-SCA method for two unimodal, four multimodal and two composite functions that were chosen as examples have been presented in Figure 2. The proposed CFAEE-SCA has been compared to the basic FA, and cutting-edge metaheuristics such as AR-GSA, GSA and RGA. From the presented convergence graphs, it can be seen that the proposed method in most cases converges faster than the other metaheuristics included in the experiments. Additionally, the proposed method is significantly superior to the basic FA metaheuristics, that in most cases stagnates while the CFAEE-SCA accelerates the convergence speed.

In order to provide more objective way for determining the performances and efficiency of the proposed method against other competitors, statistical tests must be conducted. Therefore, the Friedman test that was introduced by Friedman (1937, 1940), together with the ranked two-way analysis of variances of the suggested approach and other implemented algorithms were conducted.

The results obtained by the eight implemented approaches on the set of 28 challenging function instances from the CEC2013 benchmark suite, including the Friedman and the aligned Friedman test, are given in the Tables 5 and 6, respectively.

According to the findings presented in Table 6, the proposed CFAEE-SCA outscored all other algorithms, together with the original FA which achieved the average rank of 133.463. Suggested CFAEE-SCA achieved an average ranking of 56.838.

Additionally, the research by Sheskin (2020) suggested the possible enhancement in terms of performance by comparing with the χ^2 value. Therefore, the Iman and Davenport's test introduced by Iman and Davenport (1980) has been applied as well. The findings of this test are presented in Table 7.

The obtained findings show a value of $2.230E + 01$ that indicates significantly better results than the F -distribution critical value ($F(9, 9 \times 10) = 2.058E + 00$). Additionally, the null hypothesis H_0 has been rejected by Iman and Davenport's test. The Friedman statistics score of ($\chi_r^2 = 1.407E + 01$) results in

better performance than the F -distribution critical value at the level of significance of $\alpha = 0.05$.

The final observation that can be drawn here is that the null hypothesis (H_0) can be rejected and that the proposed CFAEE-SCA is obviously the best algorithm in the conducted tests.

As both executed statistical tests rejected the null hypothesis, the next type of test, namely the Holm's step-down procedure has been performed. This procedure is a non-parametric post-hoc method. The results of this procedure have been presented in Table 8.

The p value is the main sorting reference for all approaches included in the experiment, and they are compared against the $\alpha/(k-i)$. The k represents the degree of freedom, and the i denotes the number of the method.

This paper used the α parameter at the levels of 0.05 and 0.1. It is worth mentioning that the values of p parameter are given in scientific notation.

The summary of the conducted Holm's procedure presented in the Table 8 indicates that the significant enhancement has been achieved by the proposed method in case of both levels of significance.

THE XGBOOST CLASSIFIER TUNING WITH CFAEE-SCA

In this section, the basic information relevant to the framework for optimising the XGBoost model by using the proposed CFAEE-SCA algorithm are shown. Later on, this section presents the results of

the proposed approach on two sets of network intrusion detection experiments. First experiment was conducted by utilising the NSL-KDD benchmark dataset, while the second experiment used more recent, UNSW-NB15 network intrusion dataset.

The CFAEE-SCA-XGBoost overview

The XGBoost is an extensible and configurable improved gradient Boosting decision tree optimiser with fast computation and good performance. It constructs Boosted regression and classification trees, which operate in parallel. It efficiently optimises the value of the objective function. According to Chen and Guestrin (2016), it works by scoring the frequency and by measuring the coverage of the impact of a selected feature on the output of a function.

XGBoost utilises additive training optimisation, where each new iteration is dependant on the result of the previous one. This is evident in the i -th iteration's objective function calculation method:

$$g_j = \partial_{\hat{y}_k^{i-1}} l(y_j, \hat{y}_k^{i-1}) \quad (23)$$

$$h_j = \partial_{\hat{y}_k^{i-1}}^2 l(y_j, \hat{y}_k^{i-1}) \quad (24)$$

$$w_j^* = -\frac{\sum g_t}{\sum h_t + \lambda} \quad (25)$$

Table 7. Friedman and Iman-Davenport statistical test results summary ($\alpha = 0.05$)

CFAEE-SCA vs AR-GSA	0.109821937	6	0.05	0.1	FALSE	FALSE

$$R(f_i) = \gamma T_i + \frac{\lambda}{2} \sum_{j=1}^T w_j^2 \quad (26)$$

$$F_o^i = \sum_{k=1}^n l(y_k, \hat{y}_k^{i-1} + f_i(x_k)) + R(f_i) + C \quad (27)$$

In Equations 23-27, g and h are the 1st and 2nd derivatives, w are the weights, R is the model's regularisation term, γ and λ are parameters for configuring the tree structure (larger values give simpler trees). F_o^i is the i -th iteration's object function, l is the loss term in that iteration, and C is a constant term. Finally, the score of the loss function, which is used to evaluate the complexity of the tree structure:

$$F_o^* = -\frac{1}{2} \sum_{j=1}^T \frac{(\sum g)^2}{\sum h + \lambda} + \gamma T \quad (28)$$

The proposed CFAEE-SCA-XGBoost model's parameters are optimised using the CFAEE-SCA algorithm. The six optimised parameters shown in Table 9. The parameters have been chosen based on the several previous published research including Jiang et al. (2020), as they have the most influence on the performances of the model. The same parameters have been optimised for both conducted experiments.

Table 9. XGBoost parameters optimised by CFAEE-SCA

Parameter	Default	Range	Details
eta	0.3	[0,1]	Learning rate
max_depth	6	[0,+∞]	Maximum depth of the tree
min_child_weight	1	[0,+∞]	Minimum leaf weight
gamma	0	[0,+∞]	Related to loss function
sub-sample	1	(0,1]	Controls sampling to prevent over-fitting
colsample_bytree	1	(0,1]	Controls feature sampling proportions

Therefore, the proposed CFAEE-SCA solution is encoding as a vector with 6 components, where each vector's parameter represents one XGBoost hyper-parameter from Table 9 which is subject to optimisation process. Some of the components are continuous (eta, gamma, sub-sample, colsample_bytree) and some are integer (max_depth and min_child_weight) and this represents a typical mixed variables NP-hard challenge. During the search process, due to the search expressions of the CFAEE-SCA optimiser, integer variables are transformed to continuous, and they are eventually transformed back to integers by using simple sigmoid transfer function.

The fitness of each solution is calculated by constructing the XGBoost model based on the solution and validating its performance on the training set, while for the global best solution (the one that establishes the best fitness on the training set), the constructed XGBoost model is validated against the testing set and these metrics are reported in the results' tables. Pipeline of proposed CFAEE-SCA-XGBoost framework is presented in Figure 3.

Experiments with NSL-KDD dataset

The proposed model was trained and tested using the NSL-KDD dataset, which was analysed for the first time in Tavallae et al. (2009). The NSL-KDD dataset can be retrieved from the following URL: <https://unb.ca/cic/datasets/nsl.html>. This dataset is prepared and used for intrusion Detection system evaluation. Dataset features are described in Protić (2018). A summary describing the main features of the dataset is shown in Table 10. The proposed model was tested with the swarm size of 100 agents throughout 800 iterations, with 8000 fitness function evaluations (FFE). This setup was proposed by Jiang et al. (2020).

Table 10. NSL-KDD Dataset Summary

Property	Description
Number of records	126,620
Number of features	41
Number of classes	2 (normal uses and attacks)
Groups of attacks	4 (Probe, DoS, U2R and R2L)
Types of attacks	38 in total (21 in training set)
Number of sets	2 (a training and a testing set)

There are five event classes which represent normal use, denial of service (DoS) attack, probe attack, user to root attack (U2R), and remote to local user (R2L). As very well documented by Protić (2018), the dataset has predefined training and testing sets, whose structure is shown in Table 11, while visual representation is provided in Figure 4.

Table 11. NSL-KDD Dataset Structure

Event Type	Training Set		Testing Set	
Normal use	67,343	53.46 %	9,711	43.08 %
DoS	45,927	36.46 %	7,456	33.07 %
Probe	11,656	9.25 %	2,421	10.74 %
U2R	52	0.04 %	200	0.89 %
R2L	995	0.79 %	2,756	12.22 %
Total	125,973		22,544	

The proposed model was tested, following instructions set up by Jiang et al. (2020), with the substituting of their optimisation algorithm with the proposed CFAEE-SCA algorithm, for this experiment.

Because of different types of data in the dataset, data-points are standardised into a continuous range:

$$d'_{ij} = \frac{d_{ij} - \frac{1}{M} \sum_{i=1}^M d_{ij}}{\frac{1}{M} \sum_{i=1}^M \left| d_{ij} - \frac{1}{M} \sum_{i=1}^M d_{ij} \right|} \quad (29)$$

In Equation 29, M represents the total number of records in the dataset, d is an individual data-point for the i -th feature of the j -th record, and d' is the corresponding data-point's standardised value. After standardising all data-points, they are normalised:

$$d''_{ij} = \frac{d'_{ij} - d_{min}}{d_{max} - d_{min}} \quad (30)$$

In Equation 30, d'' is the normalised value of the corresponding d' data-point. d_{min} and d_{max} are the minimum and maximum values of the j -th feature.

The proposed model is evaluated using precision, recall, f-score, and the P-R curve. The P-R curve is used instead of the ROC curve due to its better ability to capture the binary event situation measurement impact, as explained by Sofaer et al. (2019). Specifically, these events happen in this dataset due to a limited number of U2R attack cases related to other events. P-R curve-based values, including the average

precision (AP), mean average precision (mAP) and macro-averaging calculations, further help evaluate the model's performance.

Experimental results of the proposed model are presented and compared to results of the solution with the pure XGBoost approach, the original FA-XGBoost and the PSO-XGBoost. The experimental setup is the same as the setup proposed in Jiang et al. (2020), that was used to reference the PSO-XGBoost results. It is important to state that the authors have implemented the PSO-XGBoost and tested it independently, by using the same conditions as in Jiang et al. (2020). Results for the FA and CFAEE-SCA supported versions of the XGBoost framework are shown in Table 12, together with the PSO-XGBoost and basic XGBoost results. The best results are marked in bold. As the presented results show, the proposed CFAEE-SCA-XGBoost approach clearly outperforms both other metaheuristics approaches for the observed classes. Additionally, it can be seen that the CFAEE-SCA-XGBoost significantly outperforms the basic XGBoost method. The basic FA-XGBoost obtained similar level of performances as PSO-XGBoost.

Table 13 shows AP values from the P-R curves of the CFAEE-SCA-XGBoost model compared to the values of XGBoost, FA-XGBoost and PSO-XGBoost models for all event types and classes. The proposed CFAEE-SCA-XGBoost approach performed better than other compared approaches for all types and classes. It is important to note that the NSL-KDD is imbalanced dataset, and the proposed CFAEE-SCA-XGBoost managed to achieve high performances (even for minority classes) for the accuracy and recall without modifying the original dataset. The PR curve of the basic XGBoost approach is shown in Figure 5, while the PR curve of the proposed CFAEE-SCA-XGBoost method is presented in Figure 6. To help visualising the difference and the improvements of the CFAEE-SCA-XGBoost method against the basic XGBoost, Figure 7 depicts the precision vs recall curve comparison between the proposed CFAEE-SCA method and the basic XGBoost implementation. Finally, Table 14 presents the values of XGBoost parameters determined by the proposed CFAEE-SCA method.

Experiments with UNSW-NB15 dataset

In the second set of experiments, the proposed model has been trained and tested by utilising the more recent UNSW-NB15 dataset, that was first proposed and analysed by Moustafa and Slay (2015) and Moustafa and Slay (2016). The UNSW-NB15 dataset can be retrieved from the following URL: <https://github.com/naviprem/ids-deep-learning/blob/master/datasets/UNSW-NB15.md>. Dataset features have been explained in Moustafa and Slay (2015).

In total, the UNSW-NB15 dataset contains 42 features, out of which 39 are numerical, and 3 are categorical (non-numeric). The UNSW-NB15 contains two main datasets: UNSW-NB15-TRAIN, utilised for training various models and the UNSW-NB15-TEST, utilised for testing purposes of the trained

Table 13. Comparison of AP values for each class.

	XGBoost	PSO-XGBoost	FA-XGBoost	CFAEE-SCA-XGBoost

min_child_weight	1.74	Min leaf weight
gamma	0.1	Related to loss function
sub-sample	0.6	Controls sampling to prevent over-fitting
colsample_bytree	0.88 s	Controls feature sampling proportions

models. The proposed model has been tested by following the instructions specified by Kasongo and Sun (2020), in order to provide common grounds to compare the proposed model against their published results. The train set was divided into two parts, namely TRAIN-1 (75% of the training set) and VAL (25% of the training set), where the first part was used for training and the second part was used for validating before proceeding to test phase.

The UNSW-NB15 is comprised of instances belonging to the following categories that cover typical network attacks: Normal, Backdoor, Reconnaissance, Worms, Fuzzers, DoS, Generic, Analysis, Shellcode and Exploits. The research by Kasongo and Sun (2020) utilises XGBoost as the filter method for feature selection, and the features are normalised by using Min-Max scaling during the data processing. This was followed by application on various machine learning models, such as support vector machine (SVM), linear regression (LR), artificial neural network (ANN), decision tree (DT) and k-nearest neighbours (kNN).

The first phase of the experiments used the full feature size (total of 42 features) for the binary and multiclass configurations. The second part of the experiments utilised the feature selection powered by XGBoost as the filter method, resulting in the reduced number of features (19), that were subsequently used for the binary and multiclass configuration (details about the reduced features vector can be found in Kasongo and Sun (2020)). The parameters used for ANN, LR, kNN, SVM and DT are summarised in Table 15. It is important to state that the authors have implemented and recreated all experiments by utilising the same conditions as in Kasongo and Sun (2020) and tested them independently, with maximum *FFE* as termination condition.

The simulation results are shown in Tables 16,17,18 and 19. As mentioned before, the results for the ANN, LR, kNN, SVM and DT were obtained through independent testing by authors and those values have been reported and compared to the values obtained by the basic XGBoost (with default parameters' values), PSO-XGBoost, FA-XGBoost and the proposed CFAEE-SCA-XGBoost. The best result in each category is marked in bold text.

Table 15. Machine learning methods' parameter settings

Method	Parameters
ANN	Adam solver, single hidden layer, <i>size</i> = {5, 10, 15, 30, 50, 100}, adaptive learning rate 0.02
LR	random state set to 10, maximum 1000 iterations
kNN	multiple models, <i>number_of_neighbours</i> = {3, 5, 7, 9, 11}
SVM	regularisation parameter <i>C</i> = 1.12, <i>gamma</i> = 'scale', <i>kernel</i> = 'rbf'
DT	multiple models, <i>maximum_depth_value</i> = {2, 5, 7, 8, 9}

Table 16 reports the findings of the experiments with different ML approaches, basic XGBoost and three XGBoost metaheuristics models for the binary classification that utilises the complete feature set of the UNSW-NB15 dataset. On the other hand, Table 17 depicts the results of the binary classification over the reduced feature set of the UNSW-NB15 dataset.

Tables 18 and 19 present the results obtained by different ML models, basic XGBoost and three XGBoost metaheuristics models for the multiclass classification that uses the complete and reduced feature vectors, respectively. In every table, Acc training represents the accuracy obtained over the training data, Acc val stands for the accuracy obtained over the validation data partition, and finally, Acc test denotes the accuracy obtained over the test data.

Table 16. Comparative results of binary classification by utilising all 42 features

Method	Acc training	Acc val	Acc test	Precision	Recall	F1-Score

CFAEE-SCA-XGBoost	0.9642	0.9539	0.9142	0.8167	0.9884	0.8891

Table 18. Comparative results of multiclass classification by utilising all 42 features

Method	Acc training	Acc val	Acc test	Precision	Recall	F1-Score
ANN	0.7988	0.7957	0.7559	0.7991	0.7557	0.7655
LR	0.7552	0.7395	0.6556	0.7693	0.6547	0.6663
kNN	0.8174	0.7681	0.7012	0.7578	0.7018	0.7202
SVM	0.5345	0.5271	0.6113	0.4749	0.6201	0.5378
DT	0.7766	0.7735	0.6601	0.7977	0.6604	0.5109
XGBoost	0.8155	0.7868	0.7395	0.7981	0.7264	0.7609
PSO-XGBoost	0.8216	0.7985	0.7592	0.8013	0.7611	0.7683
FA-XGBoost	0.8233	0.8007	0.7604	0.8028	0.7626	0.7698
CFAEE-SCA-XGBoost	0.8247	0.8029	0.7630	0.8045	0.7654	0.7724

The experimental findings over the UNSW-NB15 IDS dataset clearly indicate the superiority of the hybrid swarm intelligence and XGBoost methods over the standard machine learning approaches. All three XGBoost variants that use metaheuristics significantly outperformed all other models, both in case of binary classification and in case of multiclass classification. Similarly, the swarm based approaches outperformed the traditional methods for both complete feature set, and for the reduced number of features.

Table 19. Comparative results of multiclass classification by utilising 19 features

Method	Acc training	Acc val	Acc test	Precision	Recall	F1-Score
ANN	0.7944	0.7890	0.7748	0.7949	0.7751	0.7725
LR	0.7252	0.7179	0.6527	0.7085	0.6526	0.6594
kNN	0.8267	0.7989	0.7232	0.7726	0.7232	0.7385
SVM	0.5358	0.5295	0.6151	0.5392	0.6150	0.5127
DT	0.7876	0.7845	0.6759	0.7967	0.6758	0.6927
XGBoost	0.7987	0.7903	0.7592	0.7931	0.7429	0.7528
PSO-XGBoost	0.8324	0.8016	0.7765	0.7993	0.7772	0.7756
FA-XGBoost	0.8347	0.8033	0.7784	0.8015	0.7796	0.7789
CFAEE-SCA-XGBoost	0.8378	0.8069	0.7803	0.8046	0.8015	0.7824

Among the three XGBoost variants that use metaheuristics for optimisation, the PSO-XGBoost achieved the third place, basic FA-XGBoost finished second, while the proposed CFAEE-SCA-XGBoost obtained the best scores on all four test scenarios by the significant margin. This conclusion further establishes the proposed CFAEE-SCA-XGBoost method as a very promising option for the intrusion detection problem.

CONCLUSIONS

This article has presented a proposed an improved FA optimisation algorithm CFAEE-SCA, that was devised with a goal to overcome the deficiencies of the basic FA metaheuristics. Several modifications have been made to the basic algorithm, including explicit exploration mechanism, gBest CLS strategy, and hybridisation with SCA to further enhance the search process. The proposed improved metaheuristics was later used to optimise the XGBoost classifier for the intrusion detection problem. The CFAEE-SCA-XGBoost framework has been proposed, based on the XGBoost classifier, with its hyper-parameters, optimised and tuned using the newly proposed CFAEE-SCA algorithm. The proposed model was trained and tested for network intrusion detection using two well-known datasets: NSL-KDD and UNSW-NB15 dataset. The proposed model, supported by the CFAEE-SCA algorithm, outperformed the variation supported by the original FA algorithm, the PSO-XGBoost and the basic implementation of the XGBoost, that were used in the comparative analysis.

The experimental results show that the CFAEE-SCA-XGBoost model obtained the best accuracy compared to the original model and suggest the potential for using swarm intelligence algorithms for NIDS. These results uncover possible future areas for research and application.
