## Abstract

The discovery of a new form of corona-viruses in December 2019, SARS-CoV-2, commonly named covid-19, has transformed the world. With health and economy issues, scientists have been focusing on understanding the dynamics of the disease, in order to provide the governments with the best policies and strategies allowing them to reduce the span of the virus. The world has been waiting for the vaccine for almost one year. In this work, we propose a new mathematical model with five compartments, including susceptible, vaccinated, infectious, asymptomatic and recovered individuals. We provide theoretical results regarding the effective reproduction number, the stability of endemic equilibrium and disease free equilibrium. We provide a numerical analysis of the model based on the Saudi case.

*keywords: COVID-19; mathematical model; vaccination; stability*

## 1 Introduction

The outbreak of several pandemics such as COVID-19, requires the development of mathematical models in order to exhibit key epidemiological features, investigate transmission dynamics, and develop adequate control policies. Mathematical modelling, when dealing with infectious diseases, allows revealing inherent patterns and underlying structures that govern outbreaks. Simple models that contain the essential components and interactions are powerful tools to test different hypotheses and understand disease control for both short and long time. The stability analysis near the free disease equilibrium will show if the apparition of new infection cases will yield to disease outbreak. Some countries such Tunisia and Jordan registered zero cases for days in Summer 2020 but the introduction of new cases resulted in critical endemic situation by Autumn.

The complex spreading patterns of COVID-19 and the various spread speed of its variants make its containing and mitigating real challenges. The existing models vary in form and complexity, but the common objective is to provide important information for global health decision makers about the disease dynamics. Driven by the observed characteristics of COVID-19, we propose a mathematical model with two infectious states. It was reported by World Health Organization that one in three people who get COVID-19 do not show any symptoms. This is a challenging problem for health authorities as the asymptomatic individuals carry the virus and may infect other people without knowing it. Moreover, consequent efforts were made worldwide since the authorisation of new vaccines by the end of 2020. By the end of November 2021, more than 50% of the world population has first dose administered and only 40% has second dose administered. In order to study the efficacy of vaccination to contain the virus spread and its negative consequences, our model include vaccinated state. The objective is to provide efficient public health policies in determining optimal vaccination strategies. Some questions have raised since the beginning of vaccination campaigns: how many individuals should

38 be vaccinated? Is the vaccine a solution to get rid of the disease permanently? These questions are  
39 related to financial and moral costs associated with the chosen governmental policy. This paper gives  
40 theoretical and numerical analysis associated with COVID-19 epidemic dynamics in order to answer  
41 these critical questions. Although we focus mainly on the Saudi case, the model structure is general  
42 and numerically adapted to any specific context without loss of validity of the qualitative results here  
43 shown.

44 In Section 2, we present the related works regarding epidemic modeling with a focus on COVID-19  
45 control strategies and particularly population vaccination. Sections 3 and 4 include model description  
46 and analysis, respectively. The numerical results are given in Section 5 and Section 6 concludes this  
47 paper.

## 48 2 Related Works

49 The mathematical modeling in epidemiology started in England, in the 18th century, when Bernoulli  
50 analyzed the mortality of smallpox. Since then, a large variety of epidemiological models have been  
51 developed [13] [19][6] [25]. In this section, we present recent works proposed in this century, impacted  
52 by several outbreaks such as Ebola, Zika, and the swine flu [7].

53 Alexander and Moghadas [2] developed a Susceptible-Infected-Recovered-Susceptible (SIRS) epi-  
54 demic model. The authors considered that the immunity acquired by the population after infection  
55 decreases over time. The dynamical behavior of the model is investigated using different types of  
56 bifurcation, including saddle-node, Hopf, and Bogdanov-Takens. The stability analysis based on the  
57 basic reproductive number and the rate of loss of natural immunity demonstrated the coexistence  
58 of two concentric limit cycles. These theoretical results have epidemiological implications such the  
59 determination of epidemic outbreak and the control the disease spread.

60 The authors of [30] investigated the Susceptible, Exposed, Infectious, Quarantine, Susceptible  
61 (SEIQS) epidemic model, with a nonlinear incidence rate. This model takes into consideration the  
62 communal sanitation measure of quarantine, aiming at avoiding broad infection. The authors pro-  
63 vided a stability analysis using codimension-1 (transcritical, saddle-node, and Hopf) and codimension-2  
64 bifurcations (Bogdanov-Takens).

65 Recently, Lu *et. al* [18] studied the the SIRS epidemic model, the same considered in [2] but with  
66 a generalized non-monotone incidence rate. The incidence rate is a function of the infection force of  
67 a disease and the number of susceptible individuals. The given formula for the incidence rate models  
68 the psychological pressure of some epidemic disease. The government is, in general, lead to take some  
69 protective measures like lockdown when the infection number becomes very high. The authors showed  
70 that the model has both repelling and attracting Bogdanov-Takens bifurcations. Moreover, from the  
71 super-critical Hopf bifurcation, the authors concluded that a disease following this model presents  
72 periodic outbreak, which is very important to understand its dynamics, in the real world.

73 The impact of treatment function was investigated in [10] using SIS model, where recovered in-  
74 dividuals become again susceptible and the incidence rate is supposed bi-linear. In the considered  
75 model, the treatment function is saturated, which results in the existence of backward bifurcation.  
76 Thus, the eradication of the disease is not only related to the reproduction number but also to other  
77 biological or epidemiological mechanisms, such as imperfect vaccine. The bifurcation analysis outlines  
78 the necessary conditions to eliminate the disease. Zhang *et. al* [31] discussed the impact of the num-  
79 ber of hospital beds on SIS epidemic model, by considering a nonlinear recovery rate. The authors  
80 calculated the basic reproduction number corresponding to their model. This number determines the  
81 condition for the disease-free equilibrium to be globally asymptotically stable.

82 The limitations of medical resources, mainly the availability of vaccinations, is modeled using a  
83 piecewise-defined function for patient treatment in [28]. This function admits a backward bifurcation

84 with limited available medical resources. The variation of vaccination threshold affects the existence  
85 of multiple steady states, crossing cycle, and generalized endemic equilibria. Similarly, Perez *et al.*  
86 [23] considered nonlinear incidence rate for a generalized SIR model. Besides, the authors assumed  
87 that the model has saturated Holling type II treatment rate and logistic growth. Non linear and  
88 saturated functions allows to represent more accurately the dynamics epidemic diseases. Similar to  
89 previous stated works, the authors revealed the importance of the basic reproduction number  $R_0$ ,  
90 whose value determines the existence of endemic equilibrium and the stability of the disease-free  
91 equilibrium. Under some conditions related to the disease transmission rate and the treatment rate,  
92 the model may undertake a backward bifurcation and a Hopf bifurcation. The above-mentioned  
93 articles considered general disease models. In the literature, we can also find specific models targeting  
94 particular disease such as avian influenza [15] and bacterial meningitis [5]. Since the declaration of  
95 World Health Organization (WHO) of the Severe Acute Respiratory Syndrome Coronavirus (SARS-  
96 CoV-2) as a pandemic on March 2020, the scientific community has been trying to understand the  
97 dynamics of this virus.

98 One of the measures to control the virus spread in to declare total or partial lockdown, forcing  
99 social distancing. The scientific community believes that the main cause of infection is the inhalation  
100 of virus droplets [14]. Gevertz *et al.* [11] modeled social distancing as a flow rate between susceptible  
101 and asymptomatic individuals. The model reveals the existence of of a critical implementation delay,  
102 when implementing social distancing mandates. A delay of two weeks is the critical threshold between  
103 infection containment and infection expansion.

104 Nadim and Chattopadhyay [21] investigated the effect of imperfect lockdown. In the adopted  
105 model, when the basic reproduction number,  $R_0$  is less than unity, the stable disease free equilibrium  
106 coexists with a stable endemic equilibrium. This means that COVID-19 undergoes backward bifur-  
107 cation. This phenomena was observed in the Kingdom of Saudi Arabia where the new cases were  
108 decreasing to reach 97 in 06, January 2021. Unfortunately, this rate reached 386 new cases, after one  
109 month, which obliged the Ministry of Health to declare partial lockdown for 10 days. The infection  
110 force is so high that the disease cannot be totally eradicated. The authors showed that under perfect  
111 lockdown, this backward bifurcation does not exist, but such condition is not possible in the real  
112 world. In [9], the authors included in their mathematical model, based on the classical SEIR, several  
113 prevention actions such as test campaign on the population and quarantining infected persons. The  
114 model took in consideration infection treatment efforts, such as vaccination and the therapy of induced  
115 cardio-respiratory complications. Besides the usual classes of the population, the authors considered  
116 two new classes, driven by specific characteristics of the virus: infected but asymptomatic patients and  
117 suspected infected individuals. The theoretical results, tuned using the Chinese case, were compared  
118 to United Kingdom case and the Italian case, showing the similarity between the model dynamics  
119 and the real epidemic behaviour. Another scientific aspect of COVID-19 is the possible transmission  
120 of the virus through contaminated surfaces. It is believed that the virus can survive several days on  
121 the surfaces depending on the material (wood, glass or plastic). Another issue faced by the govern-  
122 ments is the awareness level of the population. Some individuals, deliberately, decide not to apply the  
123 precautionary measures, mainly wearing mask and respecting social distancing [16].

124 The issue of the efficiency of social distancing and rapid testing strategies against the pandemic was  
125 examined in [1], where the authors extended the standard SEIR model. The authors considered also  
126 the problem of undetected asymptomatic individuals, who have no symptoms but participate actively  
127 to virus spread. Furthermore, the limitation of medical resources was incorporated to the model. The  
128 theoretical findings emphasized the role of the basic reproduction number  $R_0$  in the existence of stable  
129 COVID-19 free and COVID-endemic equilibrium points. This conclusion is contested by Mohd and  
130 Sulaiman [20], who studied the SIRS model with limited medical resources and false detection issues.  
131 The authors showed that the condition of reducing the basic reproduction number under the unity

132 value is necessary to eliminate the disease but not sufficient.

133 Since the authorization COVID-19 vaccines, several research works focused on giving insight to  
 134 mathematical characteristic of virus spread after population vaccination. Algehyne *et al.* [3] used  
 135 nonlinear functional analysis and fractal fractional derivative to model the evolution over time of four  
 136 compartments: susceptible, infected, infected positive tested, and recovered. The Spanish case was  
 137 investigated in [17] using also fractional derivatives. It is important to highlight that these works  
 138 do not consider vaccinated state as a separate compartment. They rather consider that the vacci-  
 139 nated individuals are moved from susceptible to recovered compartment. The vaccinated individuals  
 140 are considered to move also from exposed state in [29].

141 Different mathematical tools are used by Rajaei *et al.* [24] to compare the effect of vaccination  
 142 with social distancing and hospitalization. Extended Kalman filter (EKF) is used for state estimation  
 143 under uncertainty.

144 Most of the existing research works developing a relationship between infectious and asymptomatic  
 145 individuals focus on estimating the model parameters using actual data [4] [11] [26] [12]. To the best  
 146 of our knowledge, our work is the first to provide to study mathematical stability of endemic and  
 147 disease free equilibrium.

### 148 3 Proposed model and effective reproduction number

149 Our objective is to derive the mathematical equations that better present the dynamics of covid-19  
 150 virus. The population is divided into five compartments: susceptible, vaccinated, infectious, asymp-  
 151 totic, and recovered; the numbers in these states are denoted by  $S(t)$ ,  $V(t)$ ,  $I(t)$ ,  $A(t)$ , and  $R(t)$ ,  
 respectively. Fig. 1 depicted the flow diagram of the disease spread.

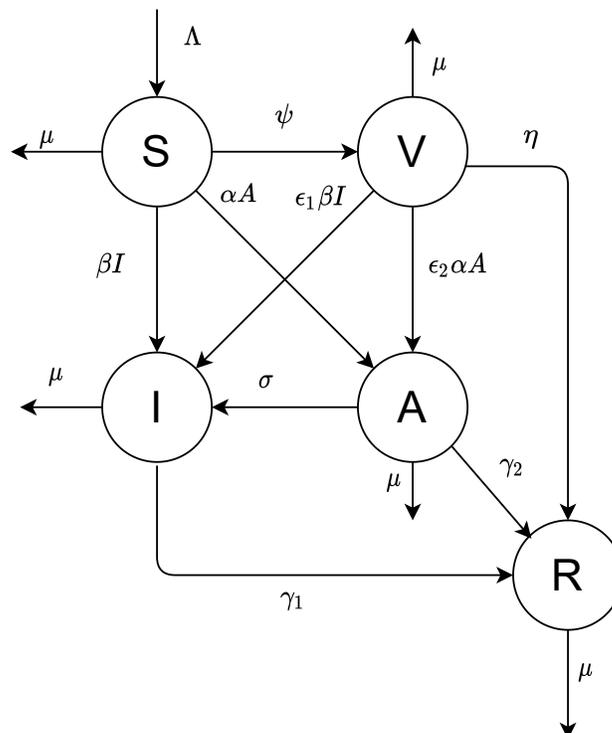

Figure 1: Proposed model.

152

153 All newborns are assumed to be susceptible. The natural recruitment and the natural death are  
 154 denoted by  $\Lambda$  and  $\mu$ , respectively. The disease-induced death rate is ignored. Susceptible individuals  
 155 are vaccinated at rate constant  $\psi$ . The parameters  $\alpha$  and  $\beta$  are the infecting rates of asymptomatic and  
 156 infectious individuals, respectively.  $\gamma_1$  and  $\gamma_2$  are the rates that the infectious and asymptomatic indi-  
 157 viduals become recovered and acquire temporary immunity, respectively. The vaccinated individuals  
 158 need a period of time to develop their immunity against the virus, represented by  $\frac{1}{\eta}$ .

159 The virus may infect vaccinated individuals but at a lower rate than susceptible individuals who  
 160 are not unvaccinated. Thus in this case, the transmission rates  $\beta$  and  $\alpha$  are multiplied by a scaling  
 161 factor  $\epsilon_1$  and  $\epsilon_2$  ( $0 \leq \epsilon_1, \epsilon_2 \leq 1$ ). Table 1 summarizes the different model parameters.

Parameter	Description
$\Lambda$	Recruitment rate of susceptible humans
$\mu$	Natural mortality rate
$\beta$	Transmission rate for Infectious
$\alpha$	Transmission rate for Asymptomatic
$\psi$	Vaccination coverage rate
$1/\eta$	Immunity development period
$\gamma_1$	Recovery rate Infectious
$\gamma_2$	Recovery rate Asymptomatic
$1/\sigma$	Period for asymptomatic individuals to develop symptoms

Table 1: Model parameters and description.

162 Based on the above assumptions and Fig. 1, we formulate the following model of differential  
 163 equations.

$$\frac{dS}{dt} = \Lambda - \mu S - \psi S - \beta IS - \alpha AS \quad (3.1a)$$

$$\frac{dV}{dt} = -\mu V + \psi S - \eta V - \epsilon_1 \beta IV - \epsilon_2 \alpha AV \quad (3.1b)$$

$$\frac{dI}{dt} = -\mu I + \beta IS + \epsilon_1 \beta IV + \sigma A - \gamma_1 I \quad (3.1c)$$

$$\frac{dA}{dt} = -\mu A + \alpha AS - \sigma A + \epsilon_2 \alpha AV - \gamma_2 A \quad (3.1d)$$

$$\frac{dR}{dt} = -\mu R + \eta V + \gamma_1 I + \gamma_2 A \quad (3.1e)$$

164 The basic reproduction number is defined as the number of secondary infections produced by a  
 165 single infectious individual during his or her entire infectious period. Since we introduce a vaccination  
 166 program in our model, it is called the effective reproduction number. The system (3.1) has always a  
 167 disease-free equilibrium, which is obtained by setting all the derivatives to zero with  $I = A = 0$ , that  
 168 yields to:  $P_0 = (S_0, I_0, A_0, R_0, V_0) = (\frac{\Lambda}{\mu + \psi}, 0, 0, \frac{\eta \psi \Lambda}{\mu(\mu + \psi)(\mu + \eta)}, \frac{\psi \Lambda}{(\mu + \psi)(\mu + \eta)})$

169 Let  $x = (I, A, V, R, S)^T$ . System (3.1) can be rewritten as  $x' = \mathcal{F}(x) - \mathcal{N}(x)$ , where  $\mathcal{F}$  be the rate  
 170 of appearance of new infections in each compartment. The progression from A to I is not considered  
 171 to be new infection, but rather the progression of an infected individual through various infectious  
 172 compartments.

$$\mathcal{F}(x) = \begin{pmatrix} \beta IS + \epsilon_1 \beta IV \\ \alpha AS + \epsilon_2 \alpha AV \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad \mathcal{N}(x) = \begin{pmatrix} (\mu + \gamma_1)I - \sigma A \\ (\mu + \sigma + \gamma_2)A \\ (\mu + \eta)V - \psi S + \epsilon_1 \beta IV + \epsilon_2 \alpha AV \\ \mu R - \eta V - \gamma_1 I - \gamma_2 A \\ -\Lambda + (\mu + \psi)S + \beta IS + \alpha AS \end{pmatrix}.$$

The infected compartments are A and I, giving  $m=2$ . With  $A=I=0$ , the Jacobian matrices of  $\mathcal{F}(x)$  and  $\mathcal{N}(x)$  at the disease-free equilibrium  $P_0$  are, respectively,

$$D\mathcal{F}(P_0) = \begin{pmatrix} F & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad DN(P_0) = \begin{pmatrix} N & 0 & 0 & 0 \\ \epsilon_1 \beta V_0 & \epsilon_2 \alpha V_0 & \mu + \eta & 0 & -\psi \\ -\gamma_1 & -\gamma_2 & -\eta & \mu & 0 \\ \beta S_0 & \alpha S_0 & 0 & 0 & \mu + \psi \end{pmatrix},$$

$$F = \begin{pmatrix} \beta S_0 + \epsilon_1 \beta V_0 & 0 \\ 0 & \alpha S_0 + \epsilon_2 \alpha V_0 \end{pmatrix}, \quad N = \begin{pmatrix} \mu + \gamma_1 & -\sigma \\ 0 & \mu + \sigma + \gamma_2 \end{pmatrix}.$$

Our developed model is similar to the two-strain model in [27] with two infectious compartments.  $FN^{-1}$ , the next generation matrix of system (3.1) has the two eigenvalues.

$$R_1 = \frac{\beta(S_0 + \epsilon_1 V_0)}{\mu + \gamma_1} = \frac{\beta\Lambda(\frac{1}{\mu + \psi} + \epsilon_1 \frac{\psi}{(\mu + \psi)(\mu + \eta)})}{\mu + \gamma_1} = \frac{\beta\Lambda(1 + \epsilon_1 \frac{\psi}{\mu + \eta})}{(\mu + \gamma_1)(\mu + \psi)}$$

$$R_2 = \frac{\alpha(S_0 + \epsilon_2 V_0)}{\mu + \gamma_2 + \sigma} = \frac{\alpha\Lambda(1 + \epsilon_2 \frac{\psi}{\mu + \eta})}{(\mu + \gamma_2 + \sigma)(\mu + \psi)} = \frac{\alpha\Lambda(\mu + \eta + \epsilon_2 \psi)}{(\mu + \gamma_2 + \sigma)(\mu + \psi)(\mu + \eta)}$$

The effective reproduction number for the system is the maximum of the two.

## 4 Model analysis

### 4.1 Existence of endemic equilibrium point

In this section, we investigate the conditions for the existence of endemic equilibria of system (3.1). Any equilibrium satisfies the following equations:

$$\Lambda - \mu S - \psi S - \beta IS - \alpha AS = 0 \quad (4.1a)$$

$$-\mu V + \psi S - \eta V - \epsilon_1 \beta IV - \epsilon_2 \alpha AV = 0 \quad (4.1b)$$

$$-\mu I + \beta IS + \epsilon_1 \beta IV + \sigma A - \gamma_1 I = 0 \quad (4.1c)$$

$$-\mu A + \alpha AS - \sigma A + \epsilon_2 \alpha AV - \gamma_2 A = 0 \quad (4.1d)$$

$$-\mu R + \eta V + \gamma_1 I + \gamma_2 A = 0 \quad (4.1e)$$

The equation (4.1d) gives the following expression:

$$S = \frac{\mu + \sigma + \gamma_2}{\alpha} - \epsilon_2 V.$$

The equation (4.1b) gives the following expression:

$$V = \frac{\psi(\mu + \sigma + \gamma_2)}{\alpha(\mu + \eta + \epsilon_1 \beta I + \epsilon_2 \alpha A + \psi \epsilon_2)}.$$

From Eq. (4.1c) and assuming  $\epsilon_1 - \epsilon_2 = 0$ , we deduce the following expressions:

$$A = \left( \frac{\mu + \gamma_1}{\sigma} - \frac{\beta(\mu + \sigma + \gamma_2)}{\alpha \sigma} \right) I = D I$$

$$S = \frac{\mu + \sigma + \gamma_2}{\alpha} \frac{(\mu + \eta + \epsilon_1 \beta I + \epsilon_2 \alpha A)}{(\mu + \eta + \epsilon_1 \beta I + \epsilon_2 \alpha A + \psi \epsilon_2)}$$

The equation (4.1a) gives the following expression:

$$\frac{\mu + \sigma + \gamma_2}{\alpha} \frac{(\mu + \eta + \epsilon_1 \beta I + \epsilon_2 \alpha D I)}{(\mu + \eta + \epsilon_1 \beta I + \epsilon_2 \alpha D I + \psi \epsilon_2)} [\mu + \psi + (\beta + \alpha D)I] = \Lambda$$

We arrange the previous expression to get the following:

$$(\epsilon_1 \beta + \epsilon_2 \alpha D)(\beta + \alpha D)I^2 + [(\mu + \eta)(\beta + \alpha D) + (\mu + \psi)(\epsilon_1 \beta + \epsilon_2 \alpha D) - \Lambda \alpha \frac{\epsilon_1 \beta + \epsilon_2 \alpha D}{\mu + \sigma + \gamma_2}]I + (\mu + \eta)(\mu + \psi) - \Lambda \alpha \frac{\mu + \eta + \psi \epsilon_2}{\mu + \sigma + \gamma_2}$$

We denote by:

$$a = (\epsilon_1\beta + \epsilon_2\alpha(\frac{\mu+\gamma_1}{\sigma} - \frac{\beta(\mu+\sigma+\gamma_2)}{\alpha\sigma}))(\beta + \alpha(\frac{\mu+\gamma_1}{\sigma} - \frac{\beta(\mu+\sigma+\gamma_2)}{\alpha\sigma}))$$

$$b = [(\mu+\eta)(\beta + \alpha(\frac{\mu+\gamma_1}{\sigma} - \frac{\beta(\mu+\sigma+\gamma_2)}{\alpha\sigma})) + (\mu+\psi)(\epsilon_1\beta + \epsilon_2\alpha(\frac{\mu+\gamma_1}{\sigma} - \frac{\beta(\mu+\sigma+\gamma_2)}{\alpha\sigma})) - \Lambda\alpha\frac{\epsilon_1\beta + \epsilon_2\alpha(\frac{\mu+\gamma_1}{\sigma} - \frac{\beta(\mu+\sigma+\gamma_2)}{\alpha\sigma})}{\mu+\sigma+\gamma_2}]$$

$$c = (\mu + \eta)(\mu + \psi) - \Lambda\alpha\frac{\mu+\eta+\psi\epsilon_2}{\mu+\sigma+\gamma_2} = (\mu + \eta)(\mu + \psi)(1 - R_2)$$

The existence of endemic equilibrium is determined by the existence of positive solutions of the quadratic equation

$$P(I) = aI^2 + bI + c = 0 \quad (4.2)$$

The number of endemic equilibria of the considered system depends on parameter values  $a$ ,  $b$ , and  $c$ . This equation may have zero, one or two solutions. We denote  $R_{20} = \frac{\alpha\Lambda}{(\mu+\gamma_2+\sigma)(\mu+\eta)}$  then

$$R_2 = R_{20}\frac{\mu+\eta+\epsilon_2\psi}{\mu+\psi}$$

We denote by  $\psi_{crit} \stackrel{def}{=} \frac{(R_{20}-1)\mu + R_{20}\eta}{1 - \epsilon_2 R_{20}}$ , where  $R_2(\psi_{crit}) = 1$ ,

Since the model parameters  $A$  and  $I$  are positive, it follows that  $D > 0$  and  $a > 0$ . Furthermore, if  $R_2 > 1$ , then  $c < 0$ . Since  $\frac{dR_2}{d\psi} = -R_{20}\frac{\eta + (1 - \epsilon_2)\mu}{(\mu + \psi)^2} < 0$  Thus,  $R_2$  is decreasing function of  $\psi$  and if  $\psi < \psi_{crit}$ , then  $R_2 > 1$ . We deduce that for  $R_2 > 1$ ,  $P(I)$  has a unique positive root.

If  $R_2 < 1$ , we have  $c > 0$  and  $\psi \geq \psi_{crit}$ . Since  $b(\psi)$  is an increasing function of  $\psi$ , if  $b(\psi_{crit}) \geq 0$ , then  $b(\psi) > 0$  for  $\psi > \psi_{crit}$ . In this case,  $P(I)$  has no positive real root and the system have no endemic equilibrium.

We consider now the case where  $b(\psi_{crit}) < 0$ . We denote by  $\Delta(\psi) \stackrel{def}{=} b^2(\psi) - 4ac(\psi)$ . If  $c(\psi_{crit}) = 0$ ,  $\Delta(\psi_{crit}) > 0$ . Since  $b(\psi)$  is an increasing linear function of  $\psi$ , there is a unique  $\bar{\psi} > \psi_{crit}$  such that  $b(\bar{\psi}) = 0$ . and  $\Delta(\psi)$  has a unique root  $\bar{\psi}$  in  $[\psi_{crit}, \bar{\psi}]$ .

$P(I)$  has two roots and the system 3.1 has two endemic equilibria for  $\psi_{crit} < \psi < \bar{\psi}$ . and  $P(I)$  has no real positive root and the system (3.1) has no endemic equilibria for  $\psi > \bar{\psi}$ .

If  $R_2 = 1$ , we have  $c=0$ . In this case, system has a unique endemic equilibrium for  $b(\psi) < 0$  and no endemic equilibrium for  $b(\psi) > 0$ .

## 4.2 Stability of disease-free equilibrium

The Jacobian matrix with respect to the system (3.1) is given by:

$$J_0(P_0) = \begin{bmatrix} -(\mu + \gamma_1) + \beta(S_0 + \epsilon_1 V_0) & \sigma & 0 & 0 & 0 \\ 0 & -(\mu + \sigma + \gamma_2) + \alpha(S_0 + \epsilon_2 V_0) & 0 & 0 & 0 \\ -\epsilon_1 \beta V_0 & -\epsilon_2 \alpha V_0 & -(\mu + \eta) & 0 & \psi \\ \gamma_1 & \gamma_2 & \eta & -\mu & 0 \\ -\beta S_0 & -\alpha S_0 & 0 & 0 & -(\mu + \psi) \end{bmatrix}.$$

$$|\lambda - J_0(P_0)| = 0.$$

The characteristic polynomial of the Jacobian matrix at DFE is given by  $\det(J_0 - \lambda I) = 0$ , where  $\lambda$  is the eigenvalue and  $I$  is  $5 \times 5$  identity matrix. Thus,  $J_0$  has eigenvalues given by:

$$\lambda_1 = -\mu$$

$$\lambda_2 = -(\mu + \eta)$$

$$\lambda_3 = -(\mu + \psi)$$

$$\lambda_4 = -(\mu + \gamma_1) + \beta(S_0 + \epsilon_1 V_0) = (\mu + \gamma_1)(R_1 - 1)$$

$$\lambda_5 = -(\mu + \sigma + \gamma_2) + \alpha(S_0 + \epsilon_2 V_0) = (\mu + \sigma + \gamma_2)(R_2 - 1)$$

All the eigenvalues are strictly negative except for  $\lambda_4$  and  $\lambda_5$ . These eigenvalues depend the sign of  $(R_2 - 1)$  and  $(R_1 - 1)$ . The stability of the DFE represents the dynamics of disease free population

237 when a small number of infected individuals introduced. Did the system stay disease free or an endemic  
238 state may appear?

239 **Theorem 1** *Based on the Theorem of [27], we have the following results. If  $R_1 > 1$  or/and  $R_2 > 1$ ,*  
240 *then  $\lambda_4$  or/and  $\lambda_5$  is/are strictly positive. In this case the DFE is unstable. If  $R_1 < 1$  and  $R_2 < 1$ ,*  
241 *then  $\lambda_4$  and  $\lambda_5$  are strictly negative. The system is locally asymptotically stable.*

## 242 5 Numerical simulations

243 In this paper, we focus on vaccination analysis in Saudi Arabia. The presented numerical simulations  
244 provide also general results that can be applied to any region. The data set is provided by King  
245 Abdullah Petroleum Studies and Research Center (KAPSARC). It includes five classes: Tested, Cases,  
246 Recoveries, Critical, Mortalities and Active and it spans the period from 04/03/2020 to 08/11/2021.  
247 It includes also important events and measures such as international flights suspension and lockdown.  
248 We use Simulink Tool in order to simulate different scenarios.

249 The death and birth rate for Saudi Arabia are estimated to be equal to 3.39 and 14.56 for 1000 per  
250 year, respectively. The vaccination campaign started on 18/12/2020 with a vaccination coverage of the  
251 total population of 0.02% to reach about 65% of the adult population fully vaccinated in November  
252 2021. The vaccination rate is considered a the percentage of the total population that get vaccinated  
253 per day. With approximately 45000 administrated doses per day and a total population of 35339000  
254 in 2021, this rate is about 0.00 127. Is this rate enough to eradicate the disease? This what we are  
255 trying to answer is this work.

256 The research report [22] provides information about asymptotic individuals for COVID-19. Most  
257 people, with no symptoms at the beginning, develop symptoms in 7-13 days, which corresponds to  
258 the  $\sigma^{-1}$ . Recall that  $\gamma_1$  is the recovery rate of infectious individuals. Interpreted as the expected  
259 value of a Poisson process,  $\gamma_1$  can be related to the needed time from the beginning of the infection  
260 till recovery [11]. With average recovery duration equal to 10 days [8], the recovery rate of infectious  
261 individuals is  $\gamma_1 = 0.1 =$ .

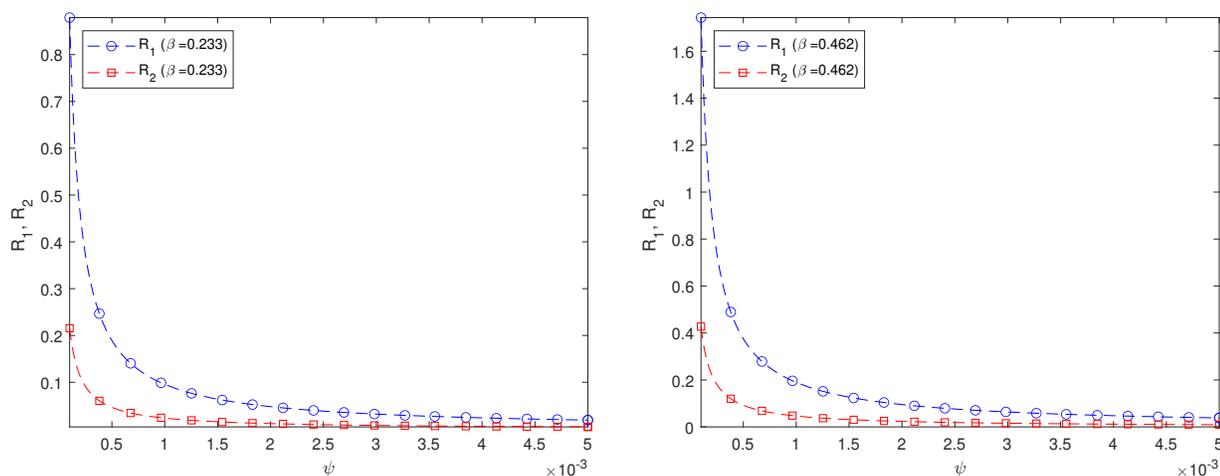

262 Let  $\omega$  denote the fraction of asymptotic individuals among positive cases. According to [22], and  
263 based on 13 studies involving 21,708 people in 2020,  $\omega = 0.17$ . Using the same methodology as in [11]  
264  $\gamma_2 = \frac{\omega}{1-\omega}\sigma \approx 0.2\sigma$ . The asymptotic people are estimated to be 42% less contagious than symptomatic  
265 individuals [22]. Thus,  $\alpha = 0.42 \beta$

Parameter	Range
$\Lambda$	14.56 per 1000 per year
$\beta$	[0.233, 0.462] [8]
$\alpha$	0.42 $\beta$
$\psi$	model parameter
$\mu$	3.39 per 1000 per year
$1/\eta$	14 days
$\gamma_1$	0.1
$\gamma_2$	0.2 $\sigma$
$1/\sigma$	[7,13] days

Table 2: Model parameters and values.

266 By 18/12/2020, considered as time 0 in this model, the number of recoveries is equal to 351722 ,  
267 the number of active cases is equal to 3014. Assuming that  $\omega = 0.17$ , the number of initial infectious  
268 with and without symptoms is equal to 2501 and 513, respectively.

269 First, we investigate the effect of the vaccination rate on the effective reproduction number defined  
 270 as the maximum of the two entities  $R_1$  and  $R_2$ . According to [8], covid-19 transmission rate  $\beta$  ranges  
 271 between 0.233 and 0.462. Fig 2a and Fig 2b show the evolution of both  $R_1$  and  $R_2$  as a function of  
 272 the vaccination rate  $\psi$  with virus transmission rate equal to 0.233 and 0.462, respectively. In both  
 273 cases,  $R_1$  corresponding to the strain of infectious individuals with symptoms is greater than  $R_2$ ,  
 274 corresponding to the strain of asymptomatic individuals. Thus the number of individuals infected by one  
 275 person carrying the virus is mainly affected by individuals showing usual symptoms. Mathematical  
 276 theoretical result confirms that the vaccine reduces the spread of the virus among the population.  
 277 We would like to highlight the fact in our model that a vaccinated individual may be infectious with  
 278 or without symptoms. This result is very important as, till the end of 2021, an important portion  
 279 of worldwide population is still opposed to vaccine. In the case of high transmission rate and low  
 280 vaccination rate,  $R_1$  is higher than 1. The disease free equilibrium is consequently unstable according  
 281 to theorem 1. For the Saudi case, when  $\beta$  is equal to 0.233,  $R_1$  and  $R_2$  are equal to 0.0797 and 0.0195,  
 282 respectively. When  $\beta$  is equal to 0.462,  $R_1$  and  $R_2$  are equal to 0.1580 and 0.0387, respectively. For  
 283 the Saudi Arabia, the effective reproduction number is less than 1, even for high transmission rate.  
 284 This result is explained by the high vaccination rate.

(a) Varying  $R_1$  and  $R_2$  as a function of  $\psi$ , (b) Varying  $R_1$  and  $R_2$  as a function of  $\psi$ ,  $\beta = 0.462$ .  
 $\beta = 0.233$ .

Figure 2: Varying  $R_1$  and  $R_2$  as a function of vaccination rate for two virus transmission rates,  $\beta = 0.233$  and  $\beta = 0.462$ .

285 Fig. 3 shows the weekly number of new active cases and recovered after infection in KSA, starting  
 286 from 18/12/2020, the date when the vaccination starts. We can see that after 12 weeks, the number of  
 287 cases raises. This behaviour was surprising for a population waiting to see the effect of vaccination.  
 288 It's only after 31 weeks that the number of new cases start to decrease. The same phenomena was  
 289 observed in both Fig. 4c and Fig. 5c. The theoretical results is conform to actual statistics. The effect  
 290 of vaccination is not immediate; it needs several weeks to observe a decrease in the number of new  
 291 infectious cases.

292 We compare the evolution in time of the five compartments (S, V, I, A, and R) presented in  
 293 our model, for two different transmission rate and with the Saudi vaccination rate. With different  
 294 dynamics at the beginning, both scenarios show a convergence to a stable state. We observe almost  
 295 similar patterns for S, V, I and R. The number of susceptible individuals  $S$  decreases slowly at the

296 beginning and then, we observe a drastic decline. Obviously, the number of recovered follows the same  
297 slow and then fast pace but in decrease. The number of vaccinated individuals  $V$  increases gradually  
298 at the beginning and then it begins to fall down. The number of infectious individuals  $I$  remain stable  
299 for a short period to witness an expansion followed by a decline. The number of asymptomatic individuals  
300 show different evolution patterns for two considered scenarios. When we set a low value for the virus  
301 transmission rate, this number immediately shrinks. However, when we set a high value for the virus  
302 transmission rate, this number increases before shrinking.

303 The effect of the transmission rate can also be observed in the amplitude of each category of  
304 individuals. When the models converge, the number of infectious and asymptomatic individuals are zero.  
305 We emphasize here our theoretical result, mentioned in Theorem 1, that states that if both  $R_1$  and  $R_2$   
306 are less than one, the disease free equilibrium is stable. This result is consistent with the simulation  
307 results. The difference between the two considered scenarios lies in the percentage of susceptible  
308 and vaccinated individuals in the equilibrium. This percentage is very low when the transmission  
309 rate is high. Although the percentages of vaccinated individuals are close, we observe a remarkable  
310 difference in the number of infectious individuals. When the transmission rate is high, almost 40% of  
311 the population is infected, which rises public health issues.

## 312 6 Conclusion

313 In this paper, we present a mathematical model for covid-19, based on the virus behaviour. Our  
314 main target is to evaluate the effect of vaccination on the population. The presence of individuals  
315 presenting no symptoms and the immunity loss are the main characteristics that make this virus  
316 different from other known and already modeled diseases. We provide analytical expression of the  
317 effective reproduction number with is a key factor to determine necessary conditions for endemic and  
318 disease free equilibrium. We supported our theoretical findings with the numerical analysis applied to  
319 the Saudi case. Recently, the scientific community is observing the new variants that show each time  
320 different patterns. We aim in the future, to develop a new model with the new observed characteristics  
321 of variants such as beta and omicron.

## 322 Acknowledgment

323 The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of  
324 Education in Saudi Arabia for funding this research work through the project number PNU-DRI-RI-  
325 20-028.
