Superoxide dismutases (SODs) are a key antioxidant enzyme family, which plays a critical function in plant growth and development. Previously, this gene family has been investigated in Arabidopsis and rice. In the present study, it was the first time for us to perform a genome-wide analysis of SOD gene family in wheat. And using bioinformatics-based methods, 26 SOD genes were identified from the whole genome of wheat, including 17 Cu/Zn-SODs, 6 Fe-SODs, and 3 Mn-SODs. The chromosomal distribution analysis revealed that SOD genes are only distributed on 2, 4 and 7 chromosomes of wheat. Phylogenetic analyses with SODs from wheat and several other species revealed that these SOD proteins can be divided into two major categories. SOD1 is mainly composed of Cu/Zn-SODs, and SOD2 is mainly composed of Fe-SODs and Mn-SODs. Gene structure and motif analysis indicated that most of the SOD genes have relatively conserved exon/intron arrangement and motif composition. Analysis of transcriptional data indicated that most of the wheat SOD genes are expressed in almost all the tested tissues and it possibly have important function in abiotic stress. Taken together, our results provide a basis for further functional research on SOD gene family in wheat and facilitate their potential applications in the genetic improvement of wheat.

## 38 INTRODUCTION

39 During the growth process, plants are affected by various adverse factors (such as drought,  
40 water damage, heat damage, cold damage, pests and diseases, heavy metal ions, etc.). A variety  
41 of abiotic and biotic stresses will result in the production of large amounts of reactive oxygen  
42 species (ROS) in plants (Razali et al, 2015). When ROS accumulates in plants, it causes  
43 oxidative stress, which destroys biological macromolecules, biofilms, etc., and can cause cell  
44 death in severe cases (Foyer&Noctor, 2005, Quan et al, 2010). At the same time, ROS as a signal  
45 molecule can regulate many physiological processes during plant growth and development, and  
46 participate in various biotic and abiotic stress responses (Mittler 2002; Pitzschke et al. 2006). In  
47 the long-term evolution process, plants form a complex antioxidant enzyme system that inhibits  
48 ROS accumulation, mainly by superoxide dismutase (SOD), catalase (CAT), peroxidase (POD),  
49 ascorbic acid (AsA), glutathione (GH), ascorbate peroxidase (APX), etc. (Alscher, Erturk &  
50 Heath, 2002; Valko et al, 2006; Sugimoto et al, 2014; Zhang et al, 2016c). The increase in plant  
51 stress resistance may be related to the antioxidant enzyme system in the body (Guo et al. 2017).  
52 SOD is widely present in living organisms. As the first enzyme involved in the scavenging  
53 reaction of reactive oxygen species, it is involved in almost all physiological and biochemical  
54 reactions against various environmental stresses in organisms, and is at the core of antioxidant  
55 enzymes (Ahmad et al, 2010; Dong et al, 2013). Fridovich and Mccor (1969) first revealed the  
56 biological function of SOD. SOD can catalyze the conversion of superoxide ( $O_2^-$ ) into oxygen  
57 ( $O_2$ ) and hydrogen peroxide ( $H_2O_2$ ) through disproportionation, and further convert  $H_2O_2$  into

water (H<sub>2</sub>O) by peroxidase and oxide enzyme to achieve active oxygen removal (Tepperman & Dunsmuir, 1990). SOD plays an important role in scavenging oxygen free radicals, preventing oxygen free radicals from disrupting cell composition, structure and function, and protecting cells from oxidative damage (Ding, 2008).

SOD constitutes the first line of defense for plant body elimination of ROS. It is ubiquitous in the plant kingdom and has many types. Many plants contain a series of SOD isozymes. SOD belongs to a class of metalloproteinases. According to the different metal cofactors in the catalytic site, it can be divided into four types: Cu/Zn-SOD, Mn-SOD, Fe-SOD, and Ni-SOD (Abreu & Cabelli, 2010; Whittaker, 2010). Fe-SOD and Mn-SOD are mainly present in lower plants, and Cu/Zn-SOD is mainly present in higher plants (Xia et al, 2015; Zeng et al, 2014). Further studies found that Fe-SOD is located in chloroplasts, Mn-SOD is located in mitochondria and peroxisomes, and Cu/Zn-SOD is mainly located in chloroplasts and cytoplasm (Dupont et al, 2010).

A large number of studies have shown that the expression of plant SOD gene is controlled by various environmental stresses, and different environmental conditions lead to differences in SOD gene expressions (Xia et al, 2015; Zhang et al, 2016c). The SOD activity in rice (Lin et al, 2009) and pea (Yan et al, 2009) was increased under salt stress. In arid environment, the activity of SOD decreased in peanuts at the early stage of stress, but under severe drought stress, SOD activity increased (Jiang & Ren, 2004). At 4 °C, the Cu/Zn-SOD activity of barley leaves did not change significantly; when the temperature dropped to -3 °C, the Cu/Zn-SOD activity increased

significantly (Moses, 2012). Under drought and saline conditions, the high drought resistance and salt tolerance of the transgenic *AtHDG11* gene increased, while the SOD activity increased, indicating the role of SOD in plant resistance. When the Arabidopsis *CBF1* (C-repeat-binding factor 1) gene were transferred to tobacco plants, the SOD activity of tobacco plants was significantly higher than that of the control, which improved the tolerance of transgenic plants to low temperature (Zhang et al, 2010). Overexpression of Mn-SOD in tobacco and maize chloroplasts enhances the protective effect of transgenic tobacco and maize on the plasma membrane and tolerance to herbicide-induced oxygen stress (Bowler et al, 1991; Breusegem et al, 1999). Taken together, these results indicate that enhanced SOD activity in plants can increase plant resistance to a variety of stresses.

Wheat is one of the world's most important food crops, accounting for more than half of total human consumption (Yin et al, 2018). The analysis of SOD gene can provide ideas for wheat genetic improvement (Zhang et al, 2009). At present, the response of wheat SOD (TaSOD) gene family and the expression of each gene under different stress conditions has not been reported at the genome-wide level. In this study, we performed genome-wide identification of SOD gene family in wheat and comprehensively analyzed their phylogenetic relationships, genome distribution, gene structure arrangement, motifs composition, expression profiles in different tissues, and their expression patterns in response to various abiotic stresses. The identification and analysis of the wheat SOD family will lay the foundation for further research on wheat stress resistance in the future.

98

## 99 MATERIALS AND METHODS

### 100 Identification of wheat SOD gene family members

101 Computer-based method was used to identify members of the SOD gene family from wheat  
102 reference genome IWGSC RefSeqv1.0 ([https://wheat-urgi.versailles.inra.fr/Seq-](https://wheat-urgi.versailles.inra.fr/Seq-Repository/Assemblies)  
103 Repository/Assemblies). A total of 8 Arabidopsis SODs (AtSODs), 12 maize SODs (ZmSODs)  
104 and 8 rice SODs (OsSODs) protein sequences were retrieved from the Arabidopsis Information  
105 Resource (TAIR10) database (<http://www.arabidopsis.org/index.jsp>), the Maize Genetics And  
106 Genomics Database (MaizeGDB) (<https://www.maizegdb.org/>), and the Rice Genome  
107 Annotation Project (RGAP) database (<http://rice.plantbiology.msu.edu/>), respectively. This  
108 information was then used to identify the SOD genes in wheat. Two methods were utilized to  
109 search the wheat protein sequences. One used a Hidden Markov Model (HMM) to search against  
110 wheat protein sequences and the other used BLASTp (E-value < 1e-5) to investigate the SOD  
111 proteins against the wheat genome, followed by Pfam (v31.05) (<http://pfam.sanger.ac.uk/search>)  
112 to supplement whether the obtained sequence contains a SOD specific structural conserved  
113 domain and ultimately determined the number of SOD gene family members.

### 114 Chromosomal locations and syntenic analysis

115 The wheat genome GFF3 gene annotation file was obtained from the wheat database  
116 IWGSCv1.0 and the gene annotation of wheat SODs (TaSODs) was extracted from the GFF3

file. The start and end location information of TaSODs in correspondence chromosomes were used to draw the physical map via the software MapInspect.

### **Proteins characterization of predicted TaSODs**

The characterization analysis of TaSODs was performed by using the protein identification and analysis tools on the ExPASy Server<sup>10</sup> (<https://prosite.expasy.org/>) (Artimo et al, 2012). The features of protein length, isoelectric point (pI), molecular weight (MW), instability index, atomic composition, and amino acid composition were predicted. The TMHMM (<http://www.cbs.dtu.dk/services/TMHMM/>) and SignalP4.1 (<http://www.cbs.dtu.dk/services/SignalP/>) online tools were used to predict transmembrane domains and signal peptides of TaSODs (Nielsen, 2017). Subcellular localization prediction of TaSODs was performed by Plant-mPLOC (<http://www.csbio.sjtu.edu.cn/cgi-bin/PlantmPLOC.cgi>) (Chou & Shen, 2010). TaSODs members were three-dimension modelled using Phyre2 (<http://www.sbg.bio.ic.ac.uk/phyre2/html/>) server at intensive mode (Kelley et al, 2015).

### **Phylogenetic analysis of TaSODs**

The phylogenetic relationship was inferred with the Maximum Likelihood (ML) method based on LG model in MEGA7.0 (Kumar, Stecher & Tamura; 2016). The midpoint rooted base tree was drawn using Interactive Tree of Life (IToL, version3.2.317, <http://itol.embl.de>).

### **Analysis of TaSODs motifs and gene structures**

135 The annotation information of TaSODs was interpreted using GSDS version 2.0  
 136 (<http://gsds.cbi.pku.edu.cn/index.php>) to obtain TaSODs gene structure, intron/exon  
 137 distribution, and intron/exon boundaries (Hu et al, 2014). Conserved TaSODs gene sequences  
 138 were identified using the MEME Suite Analysis (version 4.9.1) and MAST Primer Search  
 139 (<http://meme-suite.org/tools>) tools (Bailey et al, 2015). Establish parameters using known SOD  
 140 protein sequences, including AtSODs, OsSODs, and ZmSODs, and then apply parameters to  
 141 identify conserved TaSODs: each sequence can comprise any number of non-overlapping  
 142 occurrences of each motif, the number of different motifs is 20, and the motif width ranges from  
 143 6 to 50 amino acids. The function of these predictive motifs were analyzed using InterPro  
 144 (<http://www.ebi.ac.uk/interpro>) and SMART (<http://coot.embl-heidelberg.de/SMART>), then use  
 145 TBtools software (<https://github.com/CJ-Chen/TBtools>) for drawing.

#### 146 **Multiple conditional transcriptome analysis of TaSODs**

147 RNA-seq data original from multiple conditional transcriptome analysis were download from  
 148 NCBI and mapped to wheat reference genome by hisat2. Then genes were assembled by  
 149 cufflinks to inspect the expression levels of TaSODs (normalized by FPKM, Fragments Per  
 150 Kilobase of exon model per Million mapped reads). R package “pheatmap” was used to draw the  
 151 heatmap of TaSODs.

152

#### 153 **RESULTS**

# Identification of SODs from wheat genome

In order to identify the wheat SOD proteins (TaSODs), 28 known SOD proteins, including 8 AtSODs, 12 ZmSODs and 8 OsSODs (Kliebenstein, Monde & Last, 1998; Dehury et al. 2013; Krishna et al, 2014), were collected as query sequences to conduct BLASTp against wheat reference genome IWGSCv1.0 (E-value < 1e-5). The candidate hits are further confirmed by Pfam and local BLASTp with core motif (E-value <1e-5) to further confirm whether the TaSODs contained the superoxide dismutase domain. Finally, our rigorous computer-based screening strategy identified 26 reliable TaSODs (Table 1), including 11, 5, 10 loci of the sub-genomics A, B, and D. At this point, 54 SODs proteins were obtained from these four plant genomes (Arabidopsis, rice, maize, and wheat), which was detailed in in supplemental information:Table S1. The sequences were renamed in ascending order based on the phylogenetic relationship of OsSODs (Liu et al, 2018). The analysis of 26 wheat SOD found 17 Cu/Zn-SODs (TaSOD1.1a-TaSOD1.11b), 6 Fe-SODs (TaSOD2.4-TaSOD2.9), and 3Mn-SODs (TaSOD2.1-TaSOD2.3). This is consistent with the protein annotation information. Furthermore, it was found that TaSOD1.1, TaSOD1.5, TaSOD1.6, TaSOD1.7, TaSOD1.8 and TaSOD1.11 have alternative splicing isoforms.

174 **Gene structure and chromosomal distribution of wheat genes encoding SOD proteins**

In order to study the gene structure of the TaSODs, we analyzed their GFF3 formatted annotation and found that all TaSODs have introns. The sequence alignment of 26 TaSODs by DNAMAN software revealed that the homology between the 26 proteins was low, and the highly conserved region was mainly concentrated at the C-terminus, which may be the key region for the function of TaSODs (Figure 1). Exon-intron structural diversities often plays a key role in the evolution of gene families and can provide additional evidence to support phylogenetic grouping (Qu & Zhu, 2006; Liu, White & Macrae, 2010). The exon-intron structure of the TaSOD genes was further examined based on its evolutionary classification. As shown in Figure 2B, all TaSOD genes contained introns in their genomic sequences in wheat, and their intron numbers ranged from 4 to 7. 7 TaSOD members (TaSOD1.9, TaSOD1.10, TaSOD1.11a, TaSOD1.11b, TaSOD2.5, TaSOD2.6, and TaSOD2.8) contained the largest number of introns (7 introns), while the smallest number was only one in TaSOD1.5b (4 introns). As expected, the SOD members in the same clade of phylogenetic tree demonstrated a very similar exon/intron distribution pattern. For example, the TaSOD2.1, TaSOD2.2 and TaSOD2.3 had the same numbers of exon/intron and similar length.

Information corresponding to TaSODs are extracted from the GFF3 reference file of the wheat genome to determine the chromosomal location of the TaSOD genes. Based on the extracted physical location (Supplemental information: Table S3), the chromosomal map of TaSOD was constructed using the software MapInspect. The SOD gene map on the wheat genome is shown

196

 210 represents the Fe\_N domain, \* symbol represents the Fe\_C domain.

Figure 3 Chromosomal localization of the 26 TaSODs genome. Different classes of TaSODs are represented in different colors. Red represents TaSOD1 and blue represents TaSOD2. **TaSODs protein features**

The amino acid sequences of 26 TaSODs proteins were submitted to the ExPASyServer10 (<http://www.expasy.org/tools/>) online analytical system for analysis of biochemical characteristics such as isoelectric point (pI), relative molecular mass (MW) and instability index (Table 1). The results showed that the TaSODs have an average theoretical pI of 6.69, and the range of pI spans from 5.22 to 9.42. Protein length analysis showed amino acids (aa) ranging from 141 to 392 with an average of 236 aa and an average molecular weight of 25.14396 kD (range from 14.1218 kD to 43.40094 kD). According to previous studies, all Cu/Zn-SODs are acidic in character, while FeSODs and MnSODs are basic or acidic in character (Dehury et al. 2013, Zhang et al. 2016a). In the present study, most of the SOD1 were acidic in character, except for two SOD1 (SOD1.6b and SOD1.7b). However, most of the SOD2 were basic proteins except for two SOD2 (SOD2.7 and SOD2.9). In addition, the GRAVY analysis showed that the

226 SOD2 subfamily were a hydrophilic protein, while the SOD1 subfamily had 6 SOD1 (TaSOD1.3,  
227 TaSOD1.5a, TaSOD1.9, TaSOD1.10, TaSOD1.11a, and TaSOD1.11b) as hydrophobin and the  
228 rest were hydrophilic proteins. Interestingly, all Cu/Zn-SODs of wheat predicted localization in  
229 cytoplasm were classified into acidic amino acids. And the subcellular localization prediction  
230 that all Fe-SODs in chloroplast were mostly alkaline amino acids, whereas all Mn-SODs were  
231 composed with alkaline amino acids and located in mitochondria.

### 232 **Phylogenetic relationship analysis**

233 To obtain a better understanding of the evolutionary history and evolutionary relationships of  
234 SOD family in wheat, a phylogenetic tree was generated using the maximum likelihood (ML)  
235 method using available full-length amino acid sequences. The phylogenetic tree revealed that  
236 these SOD proteins could be classified into two major groups: SOD1 and SOD2. And we found  
237 that the SOD1 subfamily is composed of Cu/Zn-SODs and the SOD2 subfamily is composed of  
238 Fe-SODs and Mn-SODs. Based on the phylogenetic tree, we could clearly observe that the SOD  
239 proteins within the same subfamily were clustered together, while Fe-SODs and Mn-SODs were  
240 divided into one sub-groups (Figure 4), implying that FeSODs and MnSODs originated from a  
241 common ancestor (Alscher, Erturk & Heath, 2002). The SOD1 group consists of 17 TaSODs  
242 (TaSOD1.1a to TaSOD1.11b), 3 from AtSODs, 6 from ZmSODs, and 5 from OsSODs. Similarly,  
243 the SOD2 proteins includes 9 TaSODs (TaSOD2.1 to TaSOD2.9), 5 AtSODs, 6 ZmSODs, and 3  
244 OsSODs. Moreover, we also could find that the dicot SODs (Arabidopsis) have more closely

245 phylogenetic relationship related to monocot SODs (wheat, rice and maize) in each clade with all  
246 plants.

247

248 Figure 4 Phylogenetic relationship of TaSODs, OsSODs, AtSODs, and ZmSODs. Protein  
249 sequences were aligned using ClustalW2 sequence alignment program and the phylogenetic tree  
250 was constructed by software MEGA7 used to create maximum likelihood (ML) under the LG  
251 model. The tree was constructed with 1,000 bootstrap replications. Different groups were marked  
252 by different colors, and the SOD from wheat, rice, maize and Arabidopsis were distinguished  
253 with different color and shape.

254 **Conserved motifs and clustering analysis of TaSODs**

255 To investigate the evolutionary relationship of SODs in wheat, a phylogenetic tree was  
 256 constructed by aligning the 26 TaSODs. These TaSODs were clustered into two groups  
 257 (TaSOD1 and TaSOD2), which was highly consistent with the types of their metal cofactors  
 258 (Figure 2A). To further examine structural diversity and predict the function of the TaSODs  
 259 protein, 20 motifs in TaSODs were found by MEME software and further annotated by  
 260 InterProScan5 (Figure 2C). Details of these 20 motifs are shown in supplemental information:  
 261 Table S2. It was reported that the SOD gene family usually contain highly conserved domain  
 262 involved in metal binding (Perry et al, 2010). The motifs 1, 2, 3, 6, 10, 11, and 17 together  
 263 constitute the SOD conserved sites. And the motif 1, 2, 10, and 13 are Cu/Zn-SODs conserved  
 264 domains, and the motif 3, 6, 11, and 17 are conserved domains of Fe-SODs and Mn-SODs.

265 The same subfamily was observed with common motifs. All TaSODs in the SOD1 subfamily  
 266 contain motifs 1 and 5. But motif 5 is not a conserved domain of TaSOD. In the SOD2 subfamily,  
 267 all members contain motifs 3 and 6. In addition, the Cu/Zn-SODs conserved domains (motif1)  
 268 were also analyzed to understand the relationship between TaSOD1 and SODs of other species.  
 269 The alignment of all Cu/Zn-SODs conserved domains of 17 TaSOD1 is described as a conserved  
 270 motif 1: [RT]-[VF]-[ST]-G-L-[AS]-[PE]-G-[LK]-H-G-[FW]-[HS]-[ILV]-[HN]-[AE]-[FL]-G-D-  
 271 [TL]-T-[NK]-G-[CA]-[NE]-S-T-G-[PK]-[HV]-[FY]-N-P-[HN]-[GND]-[KL]-[LS]-[HS]-[GD]-  
 272 [AK]-P. This result shows eight conserved Glycine (G), Leucine (L), Histidine (H), Aspartic acid  
 273 (D), Serine (S), Threonine (T), Asparagine (N), Proline (P) in the Cu/Zn-SODs conserved  
 274 domains motif. And the conserved motif of Fe-SODs and Mn-SODs conserved domains site is

described as motif3: [DKE]-[GS]-V-[AS]-[TW]-[FI]-[GK]-[LQ]-[PQT]-[DP]-[LP]-P-Y-[DKP]-  
[TA]-[DG]-A-L-E-P-[YA]-[IMY]-S-[GKR]-[ER]-[AI]-[VM]-[ER]-[LQ]-H-[WH]-[GQ]-[KV]-  
H-[QH]-[AQ]-[TG]-[YH]-V and motif 6: [RK]-L-[ES]-[VI]-[ESV]-[HKT]-[TS]-[PR]-N-[AQ]-  
[ID]-[NP]-[LV]-[AT]-[FKW]-G-[DH]-[IS]-P-[LI]-[LI]-[AG]-[IL]-D-[VL]-W-E-H-A-Y-Y-L-  
[DQ]-Y-[KE]-[ND]-[DRV]-R-[AP]-[DET]. This result shows that motif3 has eight conserved  
Valine (V), Proline (P), Tyrosine (Y), Alanine (A), Leucine (L), Glutamic acid (E), Serine (S),  
Histidine (H). It was further found that the motif 6 included the conserved metal-binding domain  
“DVWEHAYY” of the Mn-SODs and Fe-SODs. The sequences, locations, and logos of the  
conserved motifs (motif 1, motif 3, and motif 6) in the TaSOD proteins were shown in Figure 5.  
The data analyses supported our results. All of the wheat genes we have identified contain  
conserved domains of the sod family. Congruent with previous studies in other plant species, the  
wheat SOD gene family contained characteristic amino acids, including a series of highly  
conserved active site residues that play roles in the sequence-specific binding of mental ions.

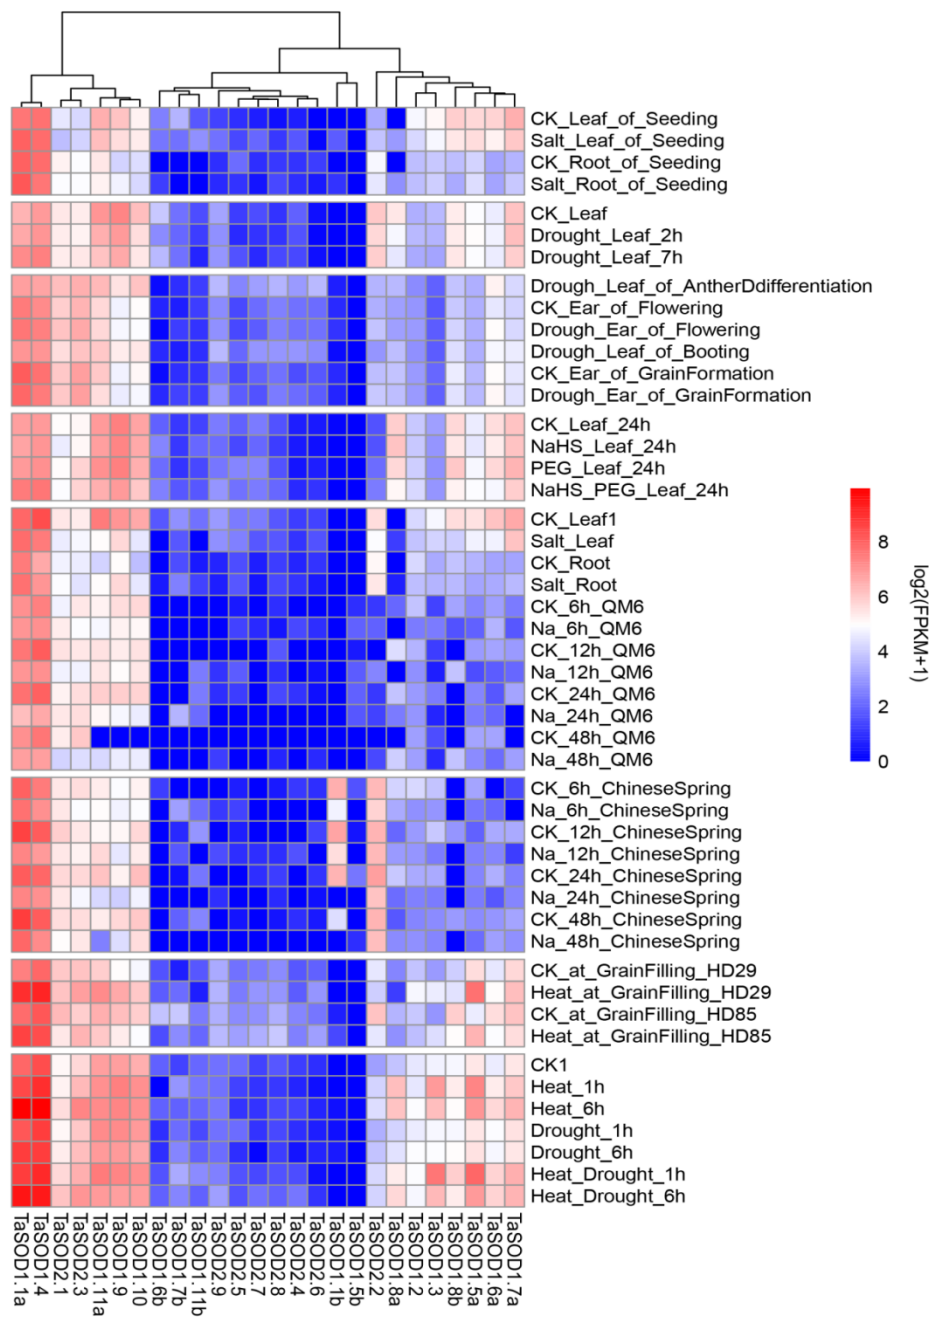

288

Figure 5 Conserved motifs of TaSODs. The number on x axis indicates the position of amino acid, and the number on Y axis indicates represents the conservation of the protein. The height of a letter indicates its relative frequency at the given position (x-axis) in the motif.

### Multiple conditional transcriptome analysis of TaSODs

We performed comprehensive microarray analysis to estimate the expression level of each TaSODs gene in different organs. RNA-seq data (Supplemental information: Table S4) original from multiple conditional transcriptome analysis were download from NCBI and mapped to wheat reference genome by hisat2. Then genes were assembled by cufflinks to inspect the expression levels of TaSODs. R package “pheatmap” was used to draw the heatmap of wheat TaSOD genes. Previous studies have shown that different types of SOD enzyme expression regulation patterns are unique and interact with each other (Dou et al, 2010). It can be observed from the Figure 6 that the SOD gene family members are expressed in different tissues, and the expression patterns of each SOD gene family member are different. The expression patterns of members of the same subclass family have a certain degree of similarity. And all TaSODs can be divided into two groups. One group contains members that are widely expressed in numerous tissues, development stages, and treatment conditions, and another contains members that are not or only highly induced in a few conditions. Interestingly, we further found that most Fe-SODs are not significantly expressed under many tissues and different abiotic environmental stresses. In addition, in the salt stress environment, the expression levels of most Cu/Zn-SODs and Mn-SODs were decreased. Meanwhile, we clearly found that Cu/Zn-SODs and Mn-SODs were

309 significantly up-regulated under drought and high temperature conditions. In particular,  
310 TaSOD1.1a and TaSOD1.4 showed the highest expression levels under drought and high  
311 temperature stress.

312

Figure 6 Multi-conditional transcriptome analysis of TaSODs. The depth of the color in the figure reflects the strength of gene expression.

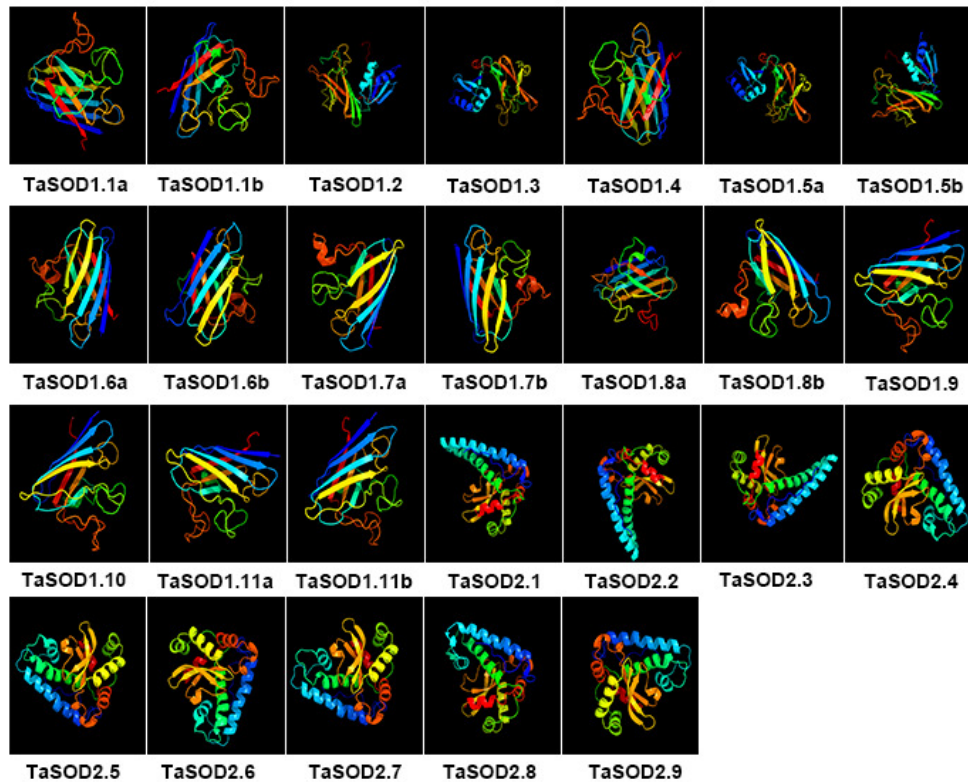

### Homology modelling of TaSODs

All 26 wheat TaSOD members were three-dimension modelled using Phyre2 server at intensive mode (Figure 7). Predicted models were based on following templates to heuristically maximize the alignment coverage, percentage identity, and confidence score for the tested sequences. Template c2q2IB were used in TaSOD1.1a TaSOD1.1b and TaSOD1.4 modelling, template c1jkqD in TaSOD1.2, TaSOD1.3, TaSOD1.5a and TaSOD1.5b modelling, template d2c9val in TaSOD1.6a, TaSOD1.6b, TaSOD1.7a, TaSOD1.7b, TaSOD1.8b, TaSOD1.9 and TaSOD1.10 modelling; template d1srda in TaSOD1.11a and TaSOD1.11b models .And template c4c7uB in TaSOD2.1, TaSOD2.2, and TaSOD2.3 modelling; template c6bejA in TaSOD2.4 ,TaSOD2.5, TaSOD2.6, TaSOD2.7, and TaSOD2.9 modelling; template c1xreB in TaSOD2.8 modelling. The quality of models was validated by Ramachandran plot analysis in which 80% of residues were in allowed region indicating the fairly good structures of models. However, it was apparent that to construct more reliable, native-like models the more experimentally solved structures are required from Superoxide Dismutase family proteins in particular from plant SODs.

In the SOD1 subfamily, the  $\beta$ -strands primarily constituted the secondary structures of modelled wheat proteins with 26-41% whereas  $\alpha$ -helices distributed with a 3-14%. However, in

332 the SOD2 subfamily, the  $\alpha$ -helices primarily constituted the secondary structures of modelled  
 333 wheat proteins with 45-60% whereas  $\beta$ -strands distributed with a 8-12%. This is similar to the  
 334 results reported in previous studies (Keerthana & Kolandaivel, 2015). Moreover, to figure out the  
 335 similarity or divergence of generated models, structures were superimposed to calculate the  
 336 percentages of structure coverage. The superimposed SOD1 subfamily models were mainly  
 337 demonstrated a 69-100% structural coverage. And the superimposed SOD2 subfamily models  
 338 were mainly demonstrated a 51-89% structural coverage. In the SOD1 subfamily, we found that  
 339 TaSOD1.1b and TaSOD1.4 structural coverage is 100%. However, in the SOD2 subfamily, some  
 340 models such as TaSOD2.5 (51%), and TaSOD2.6 (51%) showed low structure similarity but  
 341 above the twilight zone (30%). Taken together, it has been implicated that SODs from each  
 342 genome donor either may have been ancestrally similar to each other or originally divergent  
 343 SODs could have been stabilized during long domestication process resulting in changes on  
 344 protein structures thereby on protein functions.

345

346 Figure 7 Predicted 3D models of TaSODs proteins. Models were generated by using Phyre2  
 347 server at intensive mode. Models were visualized by rainbow color from N to C terminus.

348

## 349 DISCUSSION

350 Superoxide dismutase (SOD) plays important roles in multiple processes of plant growth and  
 351 resistance against environment stresses. However, only a tiny fraction of SOD genes have been  
 352 identified in plants. Genome-wide analysis is an important approach for elucidating the  
 353 biological roles of the SOD gene family members in given plant species. SOD gene family has  
 354 been reported to be widely distributed in different plant species, such as Arabidopsis

(Kliebenstein, Monde & Last, 1998), longan (Lin & Lai, 2013), rice (Dehury et al, 2013, Krishna et al, 2014), poplar (Molina et al, 2013), banana (Feng et al, 2015), pear (Wang et al, 2018), tomato (Feng et al, 2015), cotton (Zhang et al, 2016a), and cucumber (Zhou et al, 2017). However, no comprehensive analysis of this gene family has been reported in wheat.

In the present study, a total of 26 SODs genes were identified in wheat, which cover all three major types of plant SOD genes, including 17 Cu/Zn-SODs, 6 Fe-SODs, and 3 Mn-SODs (Table 1). The number of SOD genes varies among plants, previous studies revealed that the numbers of SOD genes in Arabidopsis, rice, sorghum, and tomato are 8 (3 Cu/Zn-SODs, 2 Mn-SODs, and 3 Fe-SODs), 8 (5 Cu/Zn-SODs, 1 Mn-SOD, and 2 Fe-SODs), 8 (5 Cu/Zn-SODs, 1 Mn-SOD, and 2 Fe-SODs), and 9 (4 Cu/Zn-SODs, 1 Mn-SOD, and 4 Fe-SODs), respectively. There are large differences in genome size, and the number of SOD genes varies among these plant species, but does not vary proportionally along with the changes in genome size. The discrepancy in the number of SOD genes in different plant species may be attributed to gene duplication, which consists of tandem and segmental duplications and plays a crucial role in the expansion of SOD genes for diversification. Gene duplication of SOD genes was also found in different plant species (Zhang et al, 2016a; Wang et al, 2016b; Wang et al, 2016b). Therefore, these results imply that TaSOD duplication events play a principal role in gene evolution.

Gene structure analysis revealed that the intron numbers of the 26 wheat SOD genes were 4-7 (Figure 2B). A previous research reported that plant SOD genes have highly conserved intron patterns, and most cytosolic and chloroplastic SODs harbor 7 introns (Fink & Scandalios, 2002).

In our study, seven members (TaSOD1.9, TaSOD1.10, TaSOD1.11a, TaSOD1.11b, TaSOD2.5, TaSOD2.6, and TaSOD2.8) were predicted to contain 7 introns (Figure 2B). The divergence of TaSOD gene structure may be due to the mechanisms including exon/intron gain/loss, exonization/pseudoexonization, and insertion/deletion according to a previous study (Xu et al, 2012), and the SOD members in the same clade of phylogenetic tree displayed similar exon-intron organization patterns (such as TaSOD1.6a and TaSOD1.8b; TaSOD2.1 and TaSOD2.3), suggesting that they may have similar functions related to various abiotic stresses.

Phylogenetic analysis of SOD proteins between wheat and 3 other plant species (Arabidopsis, maize, and rice) showed that the SODs could be divided into two groups of Cu/Zn-SODs and FeSODs/Mn-SODs, which is consistent with the results of previous reports (Wang et al, 2016b; Liu et al, 2018). Most of the subcellular localization data of SODs supported the phylogenetic data. All Cu/Zn-SODs were grouped in the subfamily SOD1 and predicted to be located in the cytoplasm. The chloroplast Fe-SODs and mitochondrial Mn-SODs were clustered into sub-group 2, respectively. In addition, phylogenetic analysis with other species of SOD found that most of the wheat SOD can find homologous sequences in Arabidopsis, maize or rice (Figure 4), suggesting that TaSODs probably have the same functions as SODs in other plant species.

Transcriptome analysis of SOD family genes revealed that various environmental stresses had a regulatory effect on the expression of TaSOD gene. Different TaSOD genes were differentially expressed under the same environmental stress, and there were also differences in the expression regulation of the same gene under different stresses. This also indicates that different TaSOD

proteins may play different mechanisms of action under adverse defense (Bolwell, 1998; Bubliy & Loeschcke, 2005). The transcriptional group treated with various stresses found that wheat SOD had the most obvious response to high temperature and drought stress. Among the 26 TaSODs genes, only 4 TaSOD (TaSOD1.1b, TaSOD1.5b, TaSOD1.6b, and TaSOD2.6) had no obvious variety. It can be seen from the treatment of different genes that the expression levels of TaSOD1.1a and TaSOD1.4 are significantly increased under high temperature and drought treatment conditions. The promoters of these genes can be further analyzed for functional analysis of potential important stress-resistant candidate genes.

## Figure 2 (on next page)

Figure 2 Phylogenetic analysis, gene structure, and conserved motifs of TaSODs

(A): The phylogenetic tree of all SOD genes in *Triticum aestivum*. The tree was created with bootstrap of 1000 by maximum likelihood (ML) method in MEGA7. (B): The exon-intron structure of SOD genes in *Triticum aestivum*. Exon-intron structure analyses were conducted using the GSDS database. Lengths of exons and introns of each TaSOD gene are displayed proportionally (Supplemental Figure S1). (C): The motif compositions of TaSODs were identified by MEME. Model exhibition of motif compositions in SOD amino acid sequences using MAST. Each motif is indicated with a specific color. ☆ symbol represents the Cu/Zn-SOD domain, ※ symbol represents the Fe\_N domain, □ symbol represents the Fe\_C domain.

# Figure 3(on next page)

Figure 3 Chromosomal localization of the 26 TaSODs genome.

Different classes of TaSODs are represented in different colors. Red represents TaSOD1 and blue represents TaSOD2.

# Sub-genomic A

# Sub-genomic B

# Sub-genomic D

# Figure 4(on next page)

Figure 4 Phylogenetic relationship of TaSODs, OsSODs, AtSODs, and ZmSODs.

Protein sequences were aligned using ClustalW2 sequence alignment program and the phylogenetic tree was constructed by software MEGA7 used to create maximum likelihood (ML) under the LG model. The tree was constructed with 1,000 bootstrap replications. Different groups were marked by different colors, and the SOD from wheat, rice, maize and Arabidopsis were distinguished with different color and shape.

● *Triticum aestivum*

▲ *Oryza sativa*

▲ *Zea mays*

■ *Arabidopsis thaliana*

## Figure 6 (on next page)

Figure 6 Multi-conditional transcriptome analysis of TaSODs

The depth of the color in the figure reflects the strength of gene expression.

# Figure 7 (on next page)

Figure 7 Predicted 3D models of TaSODs proteins.

Models were generated by using Phyre2 server at intensive mode. Models were visualized by rainbow color from N to C terminus.
