ABSTRACT

Background: Chronic diseases have become a global public health issue, and mass media campaigns are often used to encourage and sustain positive behavior change. Our aim was to evaluate the effect of public service advertising on the awareness of Chongqing citizens.

Methods: The theme of the public service advertisement launched in Chongqing was “being healthy, being away from chronic diseases.” A self-designed questionnaire was used in an outdoor intercept survey to collect information about the perception of citizens toward the effect of the advertisement on cognitive situations.

Results: A total of 985 valid questionnaires were received. Respondents had good understanding of chronic disease (23.6±4.1, total score: 30), but only 58.4% of participants thought cancer is one type of chronic disease. The awareness of cancer as a chronic disease among the group who had seen this advertisement (63.6%) was higher than that of the group who had not seen the advertisement (56.5%) (p=0.046). After watching the advertisement, approximately 77.4% of participants attempted to remind their family and friends to prevent chronic diseases, roughly 78.2% tried to persuade their family and friends to change their unhealthy lifestyle habits, and 73.2% of participants reported that it increased the possibility of their own lifestyle change. Logistic regression analysis indicates that occupation, educational level, watching the advertising through TV, watching the advertising through indoor LED screen, and watching the advertising through mobile TV affected the three post-viewing behavior changes.

Conclusion: The public service advertisement achieved a certain knowledge propaganda effect. It may help change awareness and improve health behavior of the public.

Key words: Public service advertisement, Chronic diseases, Health; Awareness, Behavior

INTRODUCTION

With the developing social economy and increasing aging population, the incidences of chronic diseases (e.g., cardiovascular and cerebrovascular diseases, diabetes, and chronic obstructive pulmonary disease(COPD) are dramatically increasing, which pose a serious threat to people’s
lives and health (Gu & Hu, 2003) The effects of chronic diseases on quality of life are also inevitable (Zhao et al., 2010). Chronic diseases have become a global public health problem (Wang, Feng & Lv, 2010). For example, according to the statistics released by China’s Ministry of Health, chronic diseases affect more than 260 million people in China accounts for 85% of 10.3 million deaths per year and 70% of the disease burdens (Kong, 2010). Chronic diseases in China will enter a “blowout phase” in the next 30 years (Nan, 2010; Fu, 2012).

Chronic diseases have already posed a substantial economic burden. In 2005, the World Health Organization (WHO) projected that Asia would experience the largest increase in death rates from cardiovascular disease, cancer, respiratory disease, and diabetes over the next 10 years. China, India, and the Russian Federation could lose billions of dollars in national income over the next 10 years. In China, the estimated accumulated losses from 2005 to 2015 amount to US$558 billion. In 2011, the World Bank estimated that without effective measures, the disease burden caused by myocardial infarction, stroke, diabetes, and COPD would increase to more than 50% of all disease burdens in the next two decades. In particular, the chronic disease burden in China would increase by 40% because of the rapid aging population (The World Bank, 2011).

Faced with the growing serious problem of chronic disease prevention and the unoptimistic view of the chronic disease situation (Ding et al., 2013; Li et al., 2003; Liu et al., 2012), taking measures to control the incidences of chronic disease in China is crucial. Authorities can carry out additional measures to improve knowledge and change attitudes and behaviors of the citizens toward chronic disease prevention. The unhealthy lifestyle and factors are the main events influencing of chronic diseases (Gao, Song & Ding, 2012). The effective health education and health promotion, to a certain extent, can change individuals’ unhealthy lifestyle and ultimately reduce the incidences of chronic diseases (Zhang, 2011).

Mass media interventions often involve campaigns by television, radio, newspapers, billboards, posters, leaflets, or booklets. Public interest advertising, which acts as a high-level advertising form, an independent social education power (Chen, 2012), and “advertising
conscience” (Zhang, 2008), is an important approach to health education and promotion. Public service advertisements are usually used to alert the public of important health issues (Grilli, 2000; Snyder, 2000; Sowden & Arblaster, 2000). Behavior change following public service advertising has been observed in many health campaigns, such as those on melanoma prevention programs (Theobald et al., 1991), gynecologic cancer (Crystale, Cynthia & Jennifer, 2014), and physical activity (Qin et al., 2014; Bauman, 2009; Wakefield, Loken & Hornik, 2010; Leavy, Rosenberg & Bull, 2014). Mostly, a conscious effort to stop smoking, which is a preventable risk factor for people with chronic diseases, is observed (Monyeki et al., 2013; Lin et al., 2013). These campaigns have achieved good results, and public interest advertising is considered an effective means to change the public’s awareness and behavior.

From November 16, 2012 to December 31, 2013, the public service advertisement “being healthy, being away from chronic diseases” produced by the Health Education Institute in Chongqing was broadcasted through Chongqing television and mobile television channels. This study aimed to evaluate the effect of this public service advertising on Chongqing citizens’ cognitive situation, explore how the audience promote and understand information, and assess the influence of publicity information on citizens’ attitudes and future behavior changes.

MATERIALS AND METHODS

Participants

Participants who met the following inclusion criteria were included: 1) literate, 2) aged 24–60, and 3) Chongqing local who lived there for at least half a year.

Public service advertisement

The public service advertisement “being healthy, being away from chronic diseases” includes three sections: 1) common types of chronic diseases, 2) the important influencing factors, and 3) the healthy lifestyle that can effectively prevent chronic diseases. It is a 30 seconds long animated video with audio.

This advertisement was broadcasted by the television station as well as a mobile bus in
Chongqing according to the following schedule: (1) from November 16, 2012 to July 30, 2013, the advertisement was aired on “Chongqing news” at 6:30 AM every day and then replayed on the news channel three times: on the same day at 10:00 PM and on the next day at 1:29 and 3:36 AM, which totals to 1020 times (4×30×8.5=1020). (2) From March 1 to June 30, 2013, Chongqing mobile television channel broadcasted the advertisement twice in the morning, at noon, and in the afternoon, every day, which amounts to 540 times (6×30×3=540). (3) From June 1 to December 31, 2013, the advertisement was broadcasted 2–3 times during “Healthy Hour” in the morning every day. From Monday to Friday, it was also broadcasted once before “Bu Jian Bu San” at 7:30 PM, which equals 630 times (3×30×7=630). In total, the advertisement was broadcasted 2190 times (1020+540+630=2190) during the entire period.

**Sampling method**

We selected 250 people each from four communities among the main city zones of Chongqing to participate in an outdoor intercept survey. To meet a diverse set of people, we chose the places where two to five people often socialize within the community, such as the city square, department stores, railway stations, hospitals, schools, and markets.

**Instrument**

Our survey used a self-designed questionnaire based on a literature review of related local and international studies. The final version of the questionnaire was obtained after repeated discussions with experts and a pilot study. The questionnaire had acceptable face and content validity.

It had three sections, namely, basic information on participants, chronic disease knowledge, and media and its influence.

Basic information: age (years), gender, residence time (months), having chronic disease, occupation, and education

Chronic disease knowledge: types of chronic disease, cause of chronic disease, healthy lifestyle for chronic disease prevention, concepts of chronic disease prevention, knowledge of hypertension and diabetes prevention, harm of smoking or secondhand smoking.
For the chronic disease knowledge section, 30 questions were included (all single-choice questions). A question answered correctly scored 1 point. Incorrect, unsure, or missing responses scored 0. The maximum score from the 30 knowledge questions was 30 units. The total mean score of knowledge was classified into three categories on the basis of the quintile scores and coded as “low,” “good,” and “excellent” for ≤60%, 61% to 80%, and >80%, respectively.

Media and its influence: exposure of public service advertising to people, personal subjective assessment of the immediate and follow-up effects of the public service advertising, and respondents’ daily media exposure frequency

Investigation method

At each data collection point, each team needed at least two people to investigate, but each interview was conducted one on one. The timing of data acquisition was arranged during different times of the day (twice a day). To obtain the information from various of people, the cycle of data acquisition was set at eight days. At the data collection point, two interviewers occupied different positions to contact the largest number of people. For a unified format of inviting people to attend the interview, the interviewer was required to say “hello” and invite every fifth passerby to participate in the survey. After a self-introduction, the interviewer showed the certificate of survey and explained the purpose of the survey. Finally, anonymous questionnaires were used to collect information with the respondents’ informed consent.

Regarding the questionnaire, each was checked by the members of the team on the basis of whether all answers before and after were consistent, complete and true. Then, the members of the team conformed to qualifications of valid questionnaires for a uniform number.

Quality control

The survey was chaired by the Chongqing Health Education Institute, which is responsible for developing a unified survey program and preparing training materials for the site survey work to provide technical support and advice. Investigators underwent unified training and conducted pre-investigation. During the actual investigation, the Chongqing Health Education
Institute organized personnel to conduct fieldwork supervision and quality control. Strict quality control measures were implemented to ensure that the survey data reflects the true situation as objectively as possible. Quality control was conducted throughout the entire investigation, including program design, training, site surveys, data management, and analysis.

**Ethics committees**

This project was reviewed and approved by the Ethical Committee of the Chongqing Medical University and Chongqing Health Education Institute. Oral consent was obtained from all participants. The participants were also informed that they could withdraw from the study at any stage.

**Statistical analysis**

Data from the questionnaires were checked carefully before double entry into the database using Epidata 3.02 software. After strict sorting, data cleaning and analyses were conducted using statistical analysis system software (version 9.2; SAS Institute, Cary, NC). All data entries were double-checked to avoid errors. Descriptive data were expressed as mean and SD (standard deviation) or percentage (%). Analysis of t-test was used to ascertain the significance of differences between continuous variables. Chi-square test was used to test differences of categorical variables between two groups. Logistic regression was used to assess the association between factors and behavior change after watching the advertisement. All statistical tests were performed using a two-sided test, and a p-value that is less than or equal to 0.05 was considered statistically significant.

**RESULTS**

**Demographic characteristics of participants**

A total of 1089 individuals were approached for this survey, but 89 did not meet the requirements (42 and 29 did not meet the requirements for age and place of residence, respectively. An additional 18 withdrew from the study). A total of 1000 questionnaires were issued to qualified people, and 985 valid questionnaires were received.

The demographic characteristics of participants are provided in Table 1. All participants
were aged between 24 and 60 years (24–44: 57.7%, 45–60: 42.3%) and lived in Chongqing for at least half a year (6–12 months: 8.8%, more than 12 months: 91.2%). All participants were divided into two groups (group 1: had seen the advertisement; group 2: had not seen the advertisement); only 261 (26.5%) reported that they have seen the advertisement. No significant difference was noted between the demographic characteristics of the two groups.

**Chronic disease knowledge**

Mean scores of chronic disease knowledge gained by participants who have or have not seen the advertisement were all good (Table 2). No significant difference existed between the two groups (24.1±4.0 vs. 23.5±4.1, *p*>0.05).

The participants had a high awareness accuracy on certain chronic disease knowledge, and no significant difference was observed between the two groups: (1) cause of chronic disease (Hyperlipidemia, hypertension, hyperglycemia: 84.9%; Overweight and obesity: 83.4%; Smoking: 86.7%; Unhealthy diet: 89.6%; Lack of exercise: 87.7%; Excessive Drinking: 88.8. *p*>0.05); (2) correct concept of chronic disease prevention (89.8% of participants chose the correct concept, that is, “the sooner the better, throughout his life,” *p*>0.05); (3) measures of hypertension prevention (87.7%~93.7%, *p*>0.05); and (4) measures of diabetes prevention (85.1%~89.9%, *p*>0.05) (data not shown).

The participants had high awareness accuracy on most types of chronic disease (Cardiovascular disease: 71.4%; Diabetes: 80.0%; Chronic respiratory disease: 83.8%), and no significant difference existed between the two groups (*p*>0.05) (Table 3). The participants’ awareness accuracy of cancer is low (Cancer: 58.4%), and the awareness of the group who had seen the advertisement (63.6%) was higher than that of the group who had not seen the advertisement (56.5%) (*p*=0.046). In addition, the participants also had high awareness accuracy on the lifestyle of chronic disease prevention (Quit smoking-limited wine: 92.5%; Rational nutrition: 92.2%; Regular life: 92.9%; Regular exercise: 94.0%; Keep the psychological balance: 86.3%), and no significant difference was noted between the two groups (*p*>0.05) (Table 4). Only 35.33% of participants thought that eating healthy products
was a good lifestyle choice to prevent chronic disease, and awareness about health products in the group who had seen the advertisement (47.1%) was higher than that of the group who had not seen the advertisement (31.1%) ($p<0.001$).

**Media and its influence**

**Exposure of public service advertising to people**

During the period of advertising, 261 participants watched the public service advertising through various ways. Those who watched it through TV and mobile TV (e.g., bus, subway, etc.) were 194 (74.3%) and 112 (42.9%), respectively.

**Personal subjective assessment of the immediate effects of the public service advertising**

A total of 69.0%, 72.8%, and 74.0% of participants reported that “advertising is related to my life,” “advertising makes me stop and think about my life,” and “advertising provides new information to me,” respectively.

**Personal subjective assessment of the follow-up effects of the public service advertising**

After watching the advertisement, 63.2% of participants discussed it with others, 78.2% noticed the risk factors of chronic diseases, 77.4% tried to remind others to prevent chronic diseases, 78.2% tried to persuade others to change their unhealthy lifestyle, and 73.2% mentioned that it increased the possibility of changing their own unhealthy lifestyle.

**Respondents’ daily media exposure frequency**

According to the survey, the daily media exposure frequency of the population in a week is 55.8%, 42.7%, and 43.5% for Internet and social media, respectively. Regarding Internet exposure, no significant difference existed between the two groups ($p>0.05$), but for television and social media exposure, significant difference was present between the two groups ($p=0.036$ and 0.011).

**Logistic regression analysis of the effects of the chronic disease advertisement on behaviors**

After its broadcast, the advertising caused behavior changes to participants, such as: (1) Discussed with others about this advertising, (2) Tried to remind others to prevent chronic
diseases, and (3) Tried to persuade others to change their unhealthy style. Several factors were considered in the modeling of the effects of the “being healthy, being away from chronic diseases” advertising, including sex, age, residential time, suffering from chronic diseases, occupation, education, and the way of viewing the advertising.

Table 5 indicates that the people who watched the advertising through indoor LED screen were more likely to discuss about the advertising with others than the people who did not watch through an indoor LED screen (OR=2.87, p=0.01). The people who watched the advertising through TV or mobile TV were more likely to remind others to prevent chronic diseases than the people who did not watch through these two means (OR=3.34, p=0.003; OR=2.20, p=0.014, respectively). The people who watched the advertising through mobile TV were more likely to try to persuade others to change their unhealthy lifestyle than the people who did not watched through this format (OR=2.79, p=0.003)

**DISCUSSION**

As the first to evaluate the premier chronic disease television campaign in Chongqing, our study revealed that participants have gained general knowledge on chronic disease. After watching the public service advertisement, more than 60% stated that it had changed their behaviors.

**Chronic disease knowledge**

According to this survey, the participants have high awareness accuracy on the knowledge on chronic disease, including the types and causes of chronic disease, the healthy lifestyle and concepts of chronic disease prevention, the knowledge of hypertension and diabetes prevention, and the harm of smoking or secondhand smoking. This result conforms to the finding of a study carried out in the Banan District of Chongqing (*Chen, Chen F&Rao,2013*). Such outcome may be related to three aspects. 1) In 2006, community health management for chronic diseases was implemented in Chongqing. 2) In 2010, Chongqing began to establish the demonstration plots for chronic diseases (*Qi et al.,2013*). The comprehensive control and prevention of chronic diseases in the demonstration plots were effective, and the remarkable
improvement on the levels of health knowledge and behaviors had been achieved. 3) Our survey was carried out in an urban district.

However, this study is not comprehensive. Only over half of the participants recognize cancer as a chronic disease, one-third thought eating health products was a good lifestyle choice to prevent chronic disease, and the group who had seen the advertisement was higher than that of the group who had not seen it. Although the public service advertising achieved a certain knowledge propaganda effect, continued health education is necessary in our city, especially where citizen awareness is not high.

**Media and its influence**

The aim of mass media campaigns is to encourage and sustain positive behavior change. Public service advertising, with its specific and vivid form, contains a profound moral content as well as the advantages of living close to the audience. Thus, this form of advertising can be easily recognized by people and complete its role in cultural integration (*Pan, 2001*).

In our study, television was the main medium for most people to watch the advertisement, whereas the last was broadcast, which may be related to advertising broadcast channels and frequency. In addition, with the development of the economy, an increasing number of people were watching mobile television rather than listening to the radio. Mobile television has become a good means of publicity, so we can increase the television and mobile television broadcast frequency. Through media, advertising on chronic disease had immediate personal effect, which caused half of the participants to think. It has also provided participants with new information; hence, increasing the intensity of advertising content rendering may be appropriate to draw the attention of more residents.

The advertisement positively influenced the participants. Most of them gave a good subjective evaluation and changed their behavior to a certain extent. Some tried to persuade others to change their bad lifestyle. The advertisement has also provided reference for future media intervention.

**Logistic regression analysis of the effects of the chronic disease advertisement on behaviors**
This advertisement caused behavior changes on its viewers. We chose three follow-up behavior changes to analyze the influencing factors by logistic regression analysis. Occupation, education, watching the advertisement through TV, watching the advertisement through indoor LED screen, and watching the advertisement through mobile TV generated the three advertisement effects. Television, indoor LED, and mobile TV were all effective means of advertising. Thus, we can make full use of these means in future media intervention campaigns. At the same time, designers of chronic disease advertising must fully consider the factors that influence the advertisement effect when planning for future advertisements.

CONCLUSIONS

The public service advertisement “being healthy, being away from chronic diseases” has achieved a certain knowledge propaganda effect. This advertisement can help participants to change their awareness, improve health behaviors related to chronic diseases, and transfer that knowledge to others. An increase in the application range of public service advertisement was also observed. At the same time, intensifying the advertising of less-known chronic disease information (e.g., cancer and health care products) can enhance the understanding of chronic diseases among the public.

Strengths and limitations of this study

The main findings indicate that respondents have gained general knowledge on chronic disease. After watching this public service advertising, more than 60% said that it changed their behaviors. To our knowledge, we are the first to evaluate the premier chronic disease television campaign in Chongqing.

Our study has a number of limitations. First, we did not assess the knowledge and attitude of the respondents before the advertisement. Second, street intercept methodology was used in our study. Although this sampling method has been used for other public health studies (Poomsrikaew, Ryan & Zerwic, 2010; Gase et al., 2014), caution should be taken when generalizing results to the entire population of Chongqing. Thirdly, the campaign reached only approximately 27% (261) of the participants, possibly because of 1) sampling error and 2)
survey place. We chose four communities among the main city zones of Chongqing, and these people have busy lives and are too far away to care about the advertisement.

ACKNOWLEDGMENTS

This project was funded by the central subsidies to local health literacy to promote action project in 2012 [NO.81]. We would like to thank Chongqing Health Education Institute, Television Chongqing Station, Chongqing Blood Center as well as Yuan Ning, Wenjie Huang, Taixia Song, Harry HX Wang, Yaojie Xie, Wentao Li, and Libin An for their contribution (coordinated or participated in field investigation).
